Opportunity, Security, and the Allied Industrial Base: A Quantitative Network Approach to Coalition Supply Chains for Energy Technologies

[Author names]*

October 2026

Abstract

No allied economy can efficiently reproduce the whole supply chain of energy technologies, so protection against concentrated suppliers must come from capabilities spread across trusted partners: managed interdependence rather than autarky. We build a framework to measure it and to stress-test it. Energy-security and economic-opportunity pillars score 219 economies in up to 33 technology–stage cells. A Strategic Index reads security as need, and an endowment screen admits extraction stages to a member's priority only where it has a resource base. A 57-member coalition is derived from UN General Assembly ideal points, agreements and world supply shares, and bilateral indices score partners as friendshoring opportunities and export markets. China is the largest exporter in 9 of the 18 traded stages. An Allied Industrial Base analysis then removes China's supply from 92 sub-sector nodes of observed 2024 trade. The coalition loses 22.9 percent of its traded electro-industrial demand; existing relationships and optimized partnerships restore 7.6 points of it, all by drawing supply from buyers outside the coalition, and new relationships add less than one point in 81 of 91 nodes. The binding problem is capacity: 37 of 70 electro-industrial nodes need new capacity, and they form 22 Sectoral Compacts whose exact minimum coalitions have three to nine countries. Battery midstream is the most common national priority (27 members), and 21 of the 57 priorities lie within 0.01 of the runner-up. The framework turns rankings into an auditable map of where trade suffices and where allies must build.

JEL codes: C43, C61, F14, F52, L52, Q48.

Keywords: allied industrial base; energy security; economic opportunity; composite indicators; friend-shoring; geopolitical alignment; supply-chain stress tests; industrial policy.

1 Introduction

Energy security used to be a matter of fuels: reserves, import routes and stocks of oil and gas. As solar panels, batteries, grids and power electronics absorb a growing share of energy investment, it is increasingly a matter of manufactured systems and of the minerals and components they are made from (Carey et al., 2025; International Energy Agency, 2024). A country can now be secure in fuels and exposed in transformers, battery materials or magnets. These manufacturing chains are concentrated. In the trade data used in this paper, China is the largest world exporter in nine of the 18 upstream and midstream technology–stage baskets that have a product definition, with shares between 19 and 44 percent, and the refining of rare earths and the manufacture of magnets and battery anode material are concentrated in China at shares close to or above 90 percent (International Energy Agency, 2025a, 2026b). Concentration is not in itself a market failure; it reflects scale economies, learning and geology. But it determines how far a disruption travels through production networks (Acemoglu et al., 2012; Carvalho et al., 2021; Baqaee and Farhi, 2019), and it turns trade into leverage. Hirschman (1945) made the point for bilateral trade dependence, and Farrell and Newman (2019) show that states with jurisdiction over the central nodes of global networks can observe, restrict or deny access to them.

The response so far has been national. Governments have returned to industrial policy on a scale not seen for decades (Juhász et al., 2024; Evenett et al., 2024), often with sourcing rules that tie subsidies to where minerals are processed and components made (Bown, 2023). National programmes are meeting economic and political limits. Several economies have targeted the same manufacturing segments without the demand or cost position to fill the plants, and announced capacity has been cancelled as prices fell (International Energy Agency, 2026b); subsidy competition reaches allies (Clausing and Wolfram, 2023); and tighter public finances make it implausible for every large economy to fund a complete green-industrial agenda (Ladislaw, 2025). Smaller economies cannot replicate the demand-led strategies of the largest ones at all (Albertone et al., 2025). Autarky is the expensive alternative. Simulations of broad relocalisation find large losses of trade and output without consistent gains in resilience, and diversification usually does more for resilience than reshoring (OECD, 2025b; Thakur-Weigold and Miroudot, 2024). Deep fragmentation into blocs is costly too, most of all for small economies (Aiyar et al., 2023; Javorcik et al., 2024).

These observations underpin the proposition of an Allied Industrial Base (Campbell and Doshi, 2025; New Energy Industrial Strategy Center, 2026). Matching China's scale across the electro-industrial supply chains is beyond any one allied economy. The premise is that allied economies jointly hold the markets, capital, resources and know-how that none holds alone, but deploy them through competing national strategies (Campbell and Doshi, 2025; New Energy Industrial Strategy Center, 2026). The working paper accordingly frames the policy goal as *managed interdependence*: each strategically important capability should be available at scale from some trusted member, with redundancy where a failure would be very costly, specialisation where scale economies and learning dominate, and open global sourcing where the risk is small (New Energy Industrial Strategy Center, 2026). Implementing it requires answers to questions that the literature mostly leaves open: which

nodes of which supply chains are severe enough to coordinate, who counts as a trusted partner, and which member should produce what (New Energy Industrial Strategy Center, 2026, Section 5).

This paper asks how a coalition of economies could allocate energy-technology supply chains among its members, technology by technology and stage by stage, and builds the measurements that such an allocation needs. The unit of analysis is a cell (i, t, s): an economy, one of eleven technologies (batteries, coal, electric grid, electric vehicles, gas, geothermal, green hydrogen, nuclear, oil, solar and wind) and one of three stages (upstream extraction, midstream processing and manufacturing, downstream deployment). Two pillars score the cells of 219 economies: Energy Security (ES), how secure an economy's supply is, and Economic Opportunity (EO), how well placed it is to compete as a producer. Both are built from rank-based S-curves of public data, among them the IEA, the Energy Institute, the U.S. Geological Survey, UN Comtrade and the Atlas of Economic Complexity (Section 3), and a cell enters a ranking only if the economy is sovereign and observed data carry at least half of its weight. A Strategic Index combines the pillars with a policy index into a within-country ranking of sectors in which security enters as *need*, favouring sectors where a country is exposed but capable; an endowment screen keeps an extraction stage out of a member's priority unless the member has the resource. The coalition is derived rather than chosen: from ideal points estimated from UN General Assembly votes (Bailey et al., 2017), membership of U.S. trade and security agreements, and shares of world supply. It has 31 core members on the U.S.-leaning side of the Assembly with GDP of at least USD 100 billion and 26 partners admitted through agreements or as major suppliers. Bilateral indices score each partner as a friendshoring opportunity, where an economy's security need in a sector meets the partner's economic opportunity on existing trade and investment ties, and as an export market, taking account of alignment and, in four manufacturing stages, of the Chinese ownership of the partner's foreign-invested plants. Finally, an Allied Industrial Base analysis stress-tests 92 sub-sector nodes of the observed 2024 trade network: it removes a dominant supplier, measures how much of the coalition's lost supply existing relationships and optimized partnerships restore, simulates standardised capacity increments where a gap remains, and groups the nodes that need joint action into Sectoral Compacts with exact minimum coalitions. Figure 1 sets out the architecture.

The paper makes four contributions. The first is measurement at the level of the supply-chain node. Security and opportunity are scored jointly, on a common scale and with a common variable architecture, for each stage of each technology; the scores decompose exactly into category and variable contributions, and a rankability rule keeps cells that rest mostly on imputation out of every ranking. Existing energy-security indices describe an energy system or a fuel, and green-complexity measures describe products (Mealy and Teytelboym, 2022; Growth Lab at Harvard University, 2024); neither pairs exposure with capability in the same cell. The second turns the pillars into priorities while keeping the normative choices visible: the need reading of security, the endowment screen, the basis of the policy index and the margin of each member's priority over its runner-up are reported with the results. The third is a rule-based coalition and bilateral layer. Alignment is measured from Assembly votes rather than asserted, the coalition and its tiers follow from stated

thresholds, and the bilateral indices carry both alignment and a first measure of the common-mode risk that arises when suppliers in different countries share Chinese parents. The fourth is a stress test of the allied supply network at the level of the sub-sector. It separates the economies protected from those that may supply them, distinguishes what existing relationships, coordinated trade and new capacity each contribute, checks trade-based capability against physical production data where they exist, and forms Sectoral Compacts only where chains, partners and policy needs cohere, with coalitions found by an exact binary program rather than by ranking. It answers the working paper's question of where coordination pays (New Energy Industrial Strategy Center, 2026) with a measured coordination dividend, and it reports no composite score. The pipeline is open and configuration-driven, and the corrections made during an end-to-end audit of an earlier version are documented in Appendix D.

Five sets of results stand out. First, the coalition is stronger on security than on opportunity. A coalition member leads 16 of the 30 security pairs and is in the top three of all 30, but the best-placed member leads only 8 of the 33 opportunity pairs, against 22 for China. The two pillars are correlated within pairs (median Spearman 0.59), largely through shared components: on the 23 pairs in which both pillars keep components of their own, the median falls from 0.55 to 0.30 when only the non-shared components are used. About 15 percent of the cells rankable on both pillars combine above-median opportunity with below-median security, the region the Strategic Index favours. Second, members' priorities concentrate on manufacturing. The index scores 3,154 cells in 174 countries, and every one of the 57 members has an allied pick: 43 are midstream, and battery midstream alone is the pick of 27. The endowment screen changes 41 picks, mostly away from upstream stages in which a member has a need but no resource. The picks are fragile: the median margin over the runner-up is 0.015, 21 picks lie within 0.01, and only five survive if security is read as strength rather than need. Third, alignment shapes the partnership rankings. Viewed from the 31 core members, the United States and Germany are the strongest partners and core members hold 24 of the top 25 places; giving the alignment component zero weight would lift China from 44th to 3rd. Fourth, the allies' exposure is a capacity problem. With China's supply removed, the 57 members lose 22.9 percent of their traded demand for electro-industrial goods (47.5 percent in batteries); existing relationships and optimized trade restore coverage only to 84.7 percent, and all of the recovery, USD 232 billion, is supply drawn from buyers outside the coalition. New or expanded relationships add less than one point of coverage in 81 of the 91 nodes, and no node is classed as a case for trade coordination: 37 of the 70 electro-industrial nodes need new capacity, and they form 22 Sectoral Compacts, all of them investment and offtake clubs, whose exact minimum coalitions have three to nine countries. Fifth, rankings are more robust than classifications. Country rankings within pairs barely move under random category weights (median within-pair Spearman 0.997 for security and 0.988 for opportunity), and an empirical test of vertical complementarities finds no out-of-sample gain from rewarding a stage for capability at adjacent stages; the AIB classes, by contrast, depend on how the shock is read: if China's purchases fall with its sales, 24 rather than 37 electro-industrial nodes need new capacity.

The results speak to some open questions of the working paper (New Energy Industrial Strategy Center, 2026, Section 10) but not to others. It answers the question of when coordination pays: against a China shock, rarely through trade alone, since the existing network already carries nearly all that trade can do, and chiefly through capacity at capable hosts, organised by coalitions of a few countries. It answers the question of how much duplication is enough only in part: a 25 percent supplier-share limit costs less than two points of coverage against the shock in 77 of the 91 nodes, but where capacity is missing no tested limit restores resilience to a second loss. The paper does not test the hypotheses that allied specialisation reaches a resilience target at lower public cost than parallel national programmes, that demand coordination matters more than subsidy coordination, or that fencing nodes dominates excluding sectors: these need cost, revenue and bankability data that the indices do not contain (Section 13).

The rest of the paper is organised as follows. Section 2 sets out the conceptual framework and notation and Section 3 the data. Section 4 presents the normalisation, imputation and rankability rules. Sections 5 and 6 construct the Energy Security and Economic Opportunity pillars, and Section 7 studies the joint space they define. Section 8 measures geopolitical alignment and derives the coalition, Section 9 builds the Policy and Strategic indices, Section 10 the bilateral indices, and Section 11 the Allied Industrial Base analysis of shocks, partnerships and Sectoral Compacts. Section 12 reports robustness analyses, and Section 13 discusses the results, next steps and limitations.

1.1 Related literature

The Allied Industrial Base lies where several literatures meet that are usually read separately (New Energy Industrial Strategy Center, 2026). We organise them by the streams that bear on its design and then turn to the measurement literatures on which the indices build.

Industrial policy and capabilities. Rodrik (2004) recast industrial policy as a process of discovery and strategic collaboration rather than the selection of winners, and Juhász et al. (2024) review a new empirical literature that is more favourable to it while stressing context, measurement and governance; text-based and intervention-level data now make policy measurable (Juhász et al., 2022; Evenett et al., 2024). The green variant rests on learning, coordination and environmental externalities (Rodrik, 2014), and its current form ties support to location (Bown, 2023; Bistline et al., 2023). This literature studies the relation between a state and its firms. The coordination failures it identifies, such as uncertain demand, missing suppliers and first-mover costs, do not stop at borders, and the governance of industrial interdependence among several states remains thinly studied. Our Policy index records the presence and density of policy by sector; it does not measure effectiveness.

Supply-chain resilience and economic security. Production-network models show that shocks to central suppliers need not average out (Acemoglu et al., 2012; Carvalho and Tahbaz-Salehi, 2019;

Baqaee and Farhi, 2019), that disruptions propagate along supply chains (Carvalho et al., 2021), and that private sourcing decisions can leave networks fragile (Elliott et al., 2022). Grossman et al. (2023) analyse the choice between diversification and reshoring, and Baldwin and Freeman (2022) separate exposure from resilience. Policy work defines a critical dependency as the combination of high disruption risk, high importance and limited substitutability (OECD, 2025a), and finds diversification generally more effective than relocalisation (OECD, 2025b; Thakur-Weigold and Miroudot, 2024). These results motivate scoring by stage, separating exposure (ES) from capability (EO), and stress-testing the allied network node by node. The AIB analysis shocks each node separately and does not model propagation along the chain, and the bilateral indices capture direct exposure only, not the indirect dependence that Freund et al. (2024) document.

Weaponized interdependence and allied scale. Farrell and Newman (2019) show how the hubs of global networks confer coercive power, which shifts attention from national market shares to network position, a modern form of the concern of Hirschman (1945). Campbell and Doshi (2025) argue that only a coalition can match China's productive scale and that alliances must pool capacity, not only political support. Friend-shoring (Yellen, 2022) and the evidence on fragmentation give this argument empirical content: trade and investment between geopolitical blocs have weakened relative to flows within them (Gopinath et al., 2025), U.S. sourcing has moved away from China toward economies that are themselves integrated with Chinese supply chains (Alfaro and Chor, 2023; Freund et al., 2024), and confining trade to aligned partners carries welfare costs (Góes and Bekkers, 2022; Javorcik et al., 2024; Aiyar et al., 2023).

Regional industrial policy and historical coordination. Albertone et al. (2025) show, for ASEAN, that cross-border industrial strategy must manage competition as well as cooperation, and that coordination without integration needs mechanisms that reveal synergies and monitor commitments. Historical cases point the same way. The Combined Boards of 1942–45 pooled the raw materials and production of the United States, the United Kingdom and Canada and allocated scarce output against total requirements (U.S. Department of State, 1942; U.S. War Production Board, 1944). Airbus combined national specialisation with shared demand and public risk-taking (European Commission, 2022; International Monetary Fund, 2024). The European Coal and Steel Community placed strategic sectors under common rules (European Union, 1951). Each worked around a concrete objective, clear roles and benefits reciprocal enough to sustain it.

Systemic bankability. Spokas et al. (2025) show that infrastructure technologies stall when any part of the surrounding system (offtake, permitting, enabling infrastructure, insurance, supply chains, delivery capacity) is missing, so that a designated capability is not a capability until it is bankable. Our indices do not measure bankability, which is the main reason the investment step of the AIB analysis is a capacity simulation rather than a project pipeline.

Competing schools. The policy debate divides into three schools (New Energy Industrial Strategy Center, 2026). The first defends multilateral openness and stresses the costs of fragmentation (Aiyar et al., 2023; OECD, 2025b). The second, closest to the Allied Industrial Base, accepts selective de-risking within managed interdependence. The third proposes a reciprocal bloc that conditions market access on balanced obligations and the exclusion of China (Cass, 2025). Our coalition rule belongs with the second: it admits nonaligned and even China-leaning economies through agreements or supply shares, and it fences off no sector as a whole.

Measurement. Four measurement literatures supply the building blocks. Energy-security indicators organise availability, dependence, diversity and affordability (Kruyt et al., 2009; Sovacool and Mukherjee, 2011; Ang et al., 2015; Jewell, 2011) and define security as the low vulnerability of vital systems (Cherp and Jewell, 2014; Winzer, 2012); mineral criticality combines supply risk with vulnerability (Graedel et al., 2012; Nassar et al., 2020; Kowalski and Legendre, 2023). Most such indices describe an energy system or a fuel, whereas ES applies their logic to each stage of each technology. Economic complexity treats exports as revealing capabilities (Balassa, 1965; Hidalgo et al., 2007; Hausmann and Klinger, 2006; Hidalgo and Hausmann, 2009; Hausmann et al., 2014), with relatedness predicting future specialisation (Hausmann et al., 2022) and applications to green products (Mealy and Teytelboym, 2022; Growth Lab at Harvard University, 2024); EO combines these signals with demand, cost, readiness and investment. The composite-indicator literature disciplines normalisation, weighting and uncertainty analysis (Nardo et al., 2008; Saisana et al., 2005; Paruolo et al., 2013), and our S-curve is the probability-weighting function of Karmarkar (1978). Alignment is measured with UN-vote ideal points (Bailey et al., 2017; Voeten, 2009), in the tradition of foreign-policy similarity measures (Signorino and Ritter, 1999) and with the bloc definitions of Gopinath et al. (2025). The AIB layer draws on supply-chain network design and disruption-aware sourcing (Geoffrion and Graves, 1974; Melo et al., 2009; Tomlin, 2006; Snyder et al., 2016), solved as lexicographic linear programs (Ehrgott, 2005). It departs from that tradition by restoring observed traded demand under explicit shocks rather than minimising cost, and by treating the allied network as emergent from bilateral relationships rather than designed.

The gap. Read together, these literatures diagnose the problem better than they allocate a response (New Energy Industrial Strategy Center, 2026, Section 5): they establish why capabilities and concentrated dependencies matter, why allied scale can offset national limits and why autarky is costly, but not who should produce what, or how much duplication suffices. Nor do they offer a common measurement architecture that connects sector priorities, partner capabilities and performance. The indices of Carey et al. (2025) were a first step. They score eleven technologies across commodities, manufacturing and deployment on energy-security risk and economic opportunity, read the joint space as four strategic postures, and rate partners as safer, stronger or more prosperous with weights 0.4, 0.2 and 0.4. This paper takes them from rankings to a stress test of the allied network. It rebuilds the pillars at the level of the cell with a rankability rule, derives the coalition from observed alignment and supply, rates every directed partnership, and adds an analysis of

observed trade that shows, node by node, where existing relationships suffice, where coordination would help, where allies must build and which countries a compact needs.

2 Conceptual framework

This section places the paper within the analytical architecture proposed for an Allied Industrial Base (New Energy Industrial Strategy Center, 2026), states which parts of that architecture the paper measures and which it leaves aside, and then defines the objects used in the rest of the paper. Figure 1 summarises the construction and Table 3 collects the notation.

2.1 The allied industrial base as a design problem

The working paper defines an Allied Industrial Base by its purpose: trusted economies coordinate strategically important capabilities so that, together, they reach a resilience and scale that none could reach efficiently alone (New Energy Industrial Strategy Center, 2026). The object is the network: a capability should exist at sufficient scale somewhere among trusted partners, not in every member. The unit of policy is the *node*, a step such as mineral refining or component manufacture, because one supply chain can warrant different treatment at different steps. And the problem is one of allocation: which capabilities should be domestic, duplicated, specialised among partners or left to global markets.

The working paper orders the decision in three steps. *Severity* asks how damaging a disruption would be and how hard substitution or recovery would be; *coordination*, whether the problem needs international action rather than private diversification or national policy; and *specialization*, where the capability should reside and what should be duplicated. The evidence is organised in five analytical layers: node criticality and severity, country capability and opportunity, partner complementarity and reciprocity, systemic bankability, and network robustness under stress. The object is a combination of capabilities, not a ranking: a partner that ranks low in isolation can be indispensable if it supplies what the network lacks.

Table 1 maps the layers onto this paper. We measure each economy's relative exposure within a node by the need term $1 - \text{ES}$ (rank-based, so it does not compare severity across nodes) and, for extraction, apply the endowment screen; capability by EO, with the Policy index recording where governments already concentrate their effort; complementarity, alignment and part of reciprocity by the coalition and the bilateral indices; and severity across nodes, the coordination step and robustness by the stress tests of the Allied Industrial Base analysis, which measure for each sub-sector node the share of the coalition's traded demand a shock removes and what existing relationships, coordinated trade and new capacity restore. Systemic bankability (Spokas et al., 2025), common-mode risk (beyond a first measure of the Chinese ownership of partners' foreign-invested plants), propagation along the chain, dynamic option value and reciprocal obligations are not modelled.

Two simplifications matter. First, our cell, a technology–stage pair, is coarser than the working paper's node: Batteries Midstream, for example, groups mineral refining, electrode materials and

Table 1: The analytical layers of an Allied Industrial Base and their counterparts in this paper

Layer	Measured here (section)	Not measured
1. Node criticality and severity	Country-relative exposure within each technology–stage pair, $1 - \mathrm{ES}_{its}$ (import dependence, supplier concentration, reserves; 5); endowment screen on extraction stages (9); shock exposure of 92 sub-sector nodes in USD of traded demand (11)	Disruption horizons, inventories, qualification and build times, end-use criticality
2. Country capability and opportunity	EO_{its} by cell (6); Policy index and Strategic Index (9)	Plant-level cost curves, pipeline capacity, workforce, tacit know-how
3. Complementarity and reciprocity	Coalition rule from UN-vote alignment, agreements and supply shares (8); Friendshore, Partnership Opportunity and Development Potential (10); the emergent AIB network, country roles and Sectoral Compacts (11)	Reciprocal obligations, export-restriction risk, market-access commitments
4. Systemic bankability	—	Offtake, price risk, permitting, enabling infrastructure, insurance, delivery capacity
5. Network robustness	Stress tests under five shocks: existing, optimized and investment responses, a supplier-share frontier and an N-1 test (11); Chinese-parent exposure in four Midstream cells (10)	Common-mode failure through shared inputs, logistics or equipment, propagation across nodes, stockpiles, recovery time, dynamic option value

Notes: Layers and their content follow New Energy Industrial Strategy Center (2026); numbers in parentheses refer to sections of this paper.

cell manufacture. It is the finest level at which both pillars can be scored for most economies from public data; the Allied Industrial Base analysis works at the finer sub-sector node where trade data allow it. Second, the coordination step is tested only for traded goods: the analysis measures a coordination dividend in each Upstream and Midstream node, while Downstream deployment, largely non-traded, enters the Strategic Index but not the Allied Industrial Base analysis.

2.2 Cells, pillars and rankability

The unit of analysis is the cell (i, t, s): an economy $i \in \mathcal{I}$, a technology $t \in \mathcal{T}$ and a stage $s \in \mathcal{S}$, where Upstream is the extraction of fuels and minerals, Midstream their processing and the manufacture of components and equipment, and Downstream deployment and end use. $\mathcal{T}$ holds the eleven headline technologies, fossil fuels included, so an economy has at most 33 cells, and $\mathcal{I}$ holds 219 economies after harmonisation, 195 sovereign states and 24 territories (Section 3).

Energy Security ES_{its} measures how secure i's supply of technology t at stage s is, higher values being more secure. It combines exposure (import dependence, the concentration of supplying markets) with resilience (reserves, production, consumption, access and investment). Economic Opportunity EO_{its} measures how well placed i is to capture value as a producer, from comparative advantage, export feasibility, demand, cost, technological readiness and investment. Security describes an economy as a user and opportunity as a producer, so the two can diverge: a fuel importer with a strong manufacturing base can be insecure Upstream and well placed Midstream. Shared components make part of their association mechanical (Section 7).

Both pillars are built in the same way (Section 4). Each raw variable x_{itsv}, oriented so that higher is better, is replaced by the S-curve of its percent rank within a comparison set g, usually the economies observed in the pair (t, s),

$$\tilde{x}_{itsv} = \phi_\gamma(r_{itsv}), \qquad \phi_\gamma(r) = \frac{r^\gamma}{r^\gamma + (1-r)^\gamma}, \qquad r_{itsv} = \frac{\mathrm{rank}_g(x_{itsv}) - 1}{n_g - 1}, \qquad \gamma = 0.5, \tag{1}$$

the probability-weighting function of Karmarkar (1978), which stretches the tails of a distribution relative to its middle. A category averages the components observed, or filled by an explicit missing-data rule, for the cell,

$$c_{itsk} = \frac{1}{|\mathcal{V}^*_{itsk}|} \sum_{v \in \mathcal{V}^*_{itsk}} \hat{x}_{itsv}, \tag{2}$$

and the pillar is the weighted mean over the categories $\mathcal{K}^P_{its}$ observed for the cell,

$$P_{its} = \frac{\sum_{k \in \mathcal{K}^P_{its}} w^P_k \, c_{itsk}}{\sum_{k \in \mathcal{K}^P_{its}} w^P_k}, \qquad P \in \{\mathrm{ES}, \mathrm{EO}\}, \tag{3}$$

with ten categories and fixed weights per pillar (2 to 6 for ES, 2 to 4 for EO). An unobserved category drops out with its weight rather than counting as zero, and each pillar decomposes exactly into category and variable contributions. A cell enters a ranking, a top-N list or the Strategic Index only if it is *rankable*: the economy is sovereign and at most half of the cell's index weight is imputed (equation (22)). This holds for 4,163 of 6,232 scored ES cells and 4,301 of 7,131 EO cells.

2.3 Policy and the Strategic Index

The Policy index POL_{its} records where a government directs its policy. It is the weighted mean of an index of the measures in the IEA Policies and Measures database tagged to the cell (weight 3, required) and a component that interacts the country's Climate Action Tracker rating with the technology's emission intensity (weight 2, where the country is rated). It covers 215 economies, 65 on both components and 150 on the IEA component alone, and the basis matters (Section 9). Measures from the New Industrial Policy Observatory enter only as a robustness variant (Section 12). The Strategic Index ranks the sectors of each country by the case for building there,

$$\mathrm{SI}_{its} = 0.2\,\mathrm{POL}^*_{its} + 0.3\,\mathrm{EO}_{its} + 0.3\,(1 - \mathrm{ES}_{its}) + 0.1\,\lambda_s + 0.1\,g_t, \tag{4}$$

where POL^*_{its} is the S-curve of POL across i's own scored sectors, the pillars enter at their cross-country levels, λ_s is a stage weight (Midstream 0.75, Upstream 0.5, Downstream 0.25) and $g_t \in [0, 1]$ rises as lifecycle greenhouse-gas intensity falls. A cell is scored only if the country has a Policy index and both pillar cells are rankable; nothing is imputed.

Security enters as *need*, for a reason of marginal value. Let V_i be the value to i of supply security in a sector, increasing and concave, and ρ_i the probability that an effort to build capacity there succeeds, increasing in opportunity and in existing policy commitment. An effort that raises security

by Δ is worth about

$$\rho_i(\mathrm{EO}_{its}, \mathrm{POL}_{its})\, V_i'(\mathrm{ES}_{its})\, \Delta, \tag{5}$$

which rises with opportunity and policy and falls with the security already attained. The index linearises this ranking, so sectors in which a country is exposed but capable rank first; reading security as strength would rank existing strengths first, which EO already describes. Equation (5) motivates the signs, not the additive form or the weights, which are normative (Decancq and Lugo, 2013); Section 12 reports the strength reading.

Each coalition member's *allied pick* is its highest-scoring Upstream or Midstream sector outside geothermal and green hydrogen. Read as need, ES gives an economy without a resource its largest need at the extraction stage, so an *endowment screen* admits an Upstream stage to the pick only if the member has recorded reserves or production of the stage's resources. The screen is a selection rule, not part of the index: values are unchanged, and 669 of the 998 scored Upstream cells lack a resource base. The Allied Industrial Base analysis uses neither the index nor the picks.

2.4 Coalition, bilateral indices and the Allied Industrial Base

The coalition. The coalition $\mathcal{N}$ is derived by rule (Section 8). Each voting economy is placed on a U.S.–China axis $s_i \in [0, 1]$ from its UN General Assembly ideal point (equation (50)), and quartiles of s_i define U.S.-leaning, nonaligned and China-leaning blocs. The 31 *core* members are the U.S.-leaning economies with GDP of at least USD 100 billion. The 26 *partners* are members of a U.S. free-trade agreement, the Indo-Pacific Economic Framework, the Minerals Security Partnership, the G7 or NATO above the same GDP floor, and major suppliers outside the China-leaning bloc without a GDP floor: at least 5 percent of world production, refining, manufacturing capacity or exports in an Upstream or Midstream stage, or at least 10 percent of world reserves of a headline mineral, fuel or uranium. With the six EU members below the GDP floor the coalition spans 63 economies, or 37 units with the EU-27 taken as one. The dyadic alignment A_{ij} (equation (51)), the probability that two economies fall on the same side of the divide, links the coalition to the bilateral layer.

Bilateral indices. For a reporter i, a partner $j \neq i$ and a pair (t, s), Friendshore FS_{ijts} scores j as a friendshoring opportunity for i: a partner in which i could invest and from which it could source to meet its security need in (t, s). It combines i's need, j's economic opportunity, i's imports from j, i's outward investment in j, the alignment A_{ij} and, in four manufacturing stages, the share of j's foreign-invested plants without Chinese parents, less a climate-policy penalty (equation (66)); it describes where investment and sourcing could go, not today's leading suppliers. Partnership Opportunity PO_{ijts} rates j as a market for i's exports, and Development Potential DP_{jts} scores partners that are not high-income economies. The Partnership Strength Index combines best-five summaries of the three with weights 0.4, 0.4 and 0.2, those of the partnership score of Carey et al. (2025); the headline averages the views of the 31 core members. Table 2 shows how security and opportunity enter each index.

Table 2: How security and opportunity enter each index

Index	Whose position	Energy security enters as	Economic opportunity enters as
Strategic Index SI_{its}	country i, deciding where to build	need of i: $1 - \mathrm{ES}_{its}$ (level), weight 0.3	capability of i: EO_{its} (level), weight 0.3
Friendshore FS_{ijts}	economy i, partner j as friendshoring opportunity	need of i, ranked across i's own cells (the same for every partner in (t, s)), weight 2 of 11	opportunity of the partner, ranked across economies in (t, s), weight 2 of 11
Partnership Opportunity PO_{ijts}	exporter i, market j	need of the market, ranked across markets, weight 1 of 7	capability of the exporter, ranked across economies, weight 3 of 7
Development Potential DP_{jts}	partner j, not high income	need of the partner, weight 1 of 10	opportunity of the partner, weight 1.5 of 10
AIB trade program	exporter e, importer m	— (exposure and coverage are measured from observed trade)	through PO_{em}, a tie-break among allocations of equal coverage
AIB host ranking	host h, investor m	through FS_{mh} (need of the investor), a tie-break among capable hosts	through FS_{mh} (opportunity of the host); hosts are gated on trade and production

Notes: Weights are nominal, before renormalisation over the components observed. Security enters as need wherever it describes the party that would gain from new supply. The AIB analysis measures exposure from observed trade and uses the indices only as tie-breaks. Sections 9, 10 and 11 give the full definitions.

The Allied Industrial Base. The AIB analysis works on the observed 2024 trade at 92 sub-sector nodes n of the ten technologies with a trade basket. The *demand scope* is the 57 coalition members, whose lost supply it seeks to restore, and the *candidate partners* are all economies with material exports. A shock removes a supplier's exports (in the headline China's, with China still buying). State A is the shock, state B the response of the 2024 relationships, each allowed at most to double, and state C optimized partnerships, in which any candidate may serve any importer; B and C are lexicographic linear programs that maximise the demand served first. With C_n the share of the scope's traded demand for node n that is served,

$$\text{coordination dividend}_n = C_n^{\mathrm{C}} - C_n^{\mathrm{B}}, \qquad \text{residual gap}_n = 1 - C_n^{\mathrm{C}}. \tag{6}$$

Where the gap is at least 5 percent, a standardised capacity increment is simulated at capable hosts, and the importers it serves are the investors of an investor–host pair. The selected trade and investment relationships form the emergent network, each node is classified as BUILD, COORDINATE, MANAGE SPECIALIZATION or LOW INTERVENTION by stated thresholds, and intervention nodes that cohere along the physical chain, in their partners and in their policy needs form Sectoral Compacts, whose minimum coalitions solve an exact binary program. Export Opportunity and Friendshore only order allocations and hosts that are equal on coverage; no index enters as a weight, and there is no composite score.

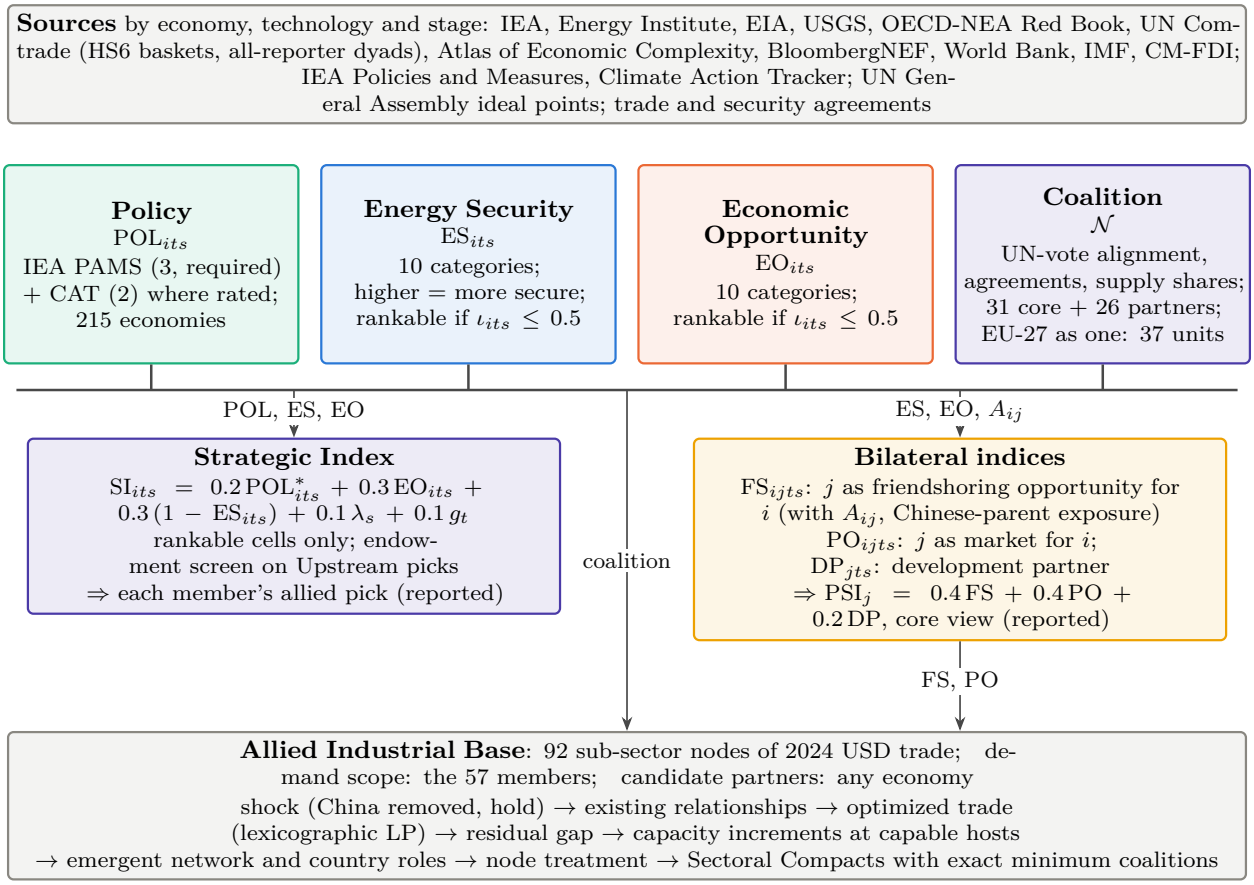

Figure 1: Architecture of the analysis. Sources feed four cell- or economy-level constructs: the Policy index, the two pillars, and the coalition, derived from alignment in the UN General Assembly, agreements and supply shares. The Strategic Index ranks each country's sectors and yields the allied picks; the bilateral indices score partners as friendshoring opportunities and export markets and are summarised in the Partnership Strength Index. The Allied Industrial Base analysis stress-tests the coalition's observed trade at 92 sub-sector nodes and forms Sectoral Compacts where joint action pays. In the terms of New Energy Industrial Strategy Center (2026), the pillars, the Policy index and the Strategic Index address relative exposure and capability, the coalition and the bilateral indices complementarity, and the AIB analysis severity, coordination, specialisation and robustness. ι_{its} is the imputed share of a cell's index weight; the Strategic Index and the Partnership Strength Index are not inputs to the AIB analysis.

Table 3: Notation

Symbol	Meaning	Defined in
Sets and indices		
$\mathcal{I}$	the 219 economies after harmonisation	Sec. 3
$\mathcal{T}$, $\mathcal{S}$	eleven headline technologies; {Upstream, Midstream, Downstream}	Sec. 2.2
$\mathcal{N}$	the 57 coalition members (31 core, 26 partners); 37 units with the EU-27 as one	Sec. 8
i, j; t, s; k, v	economy (reporter), partner; technology, stage; category, variable	
n; e, m	AIB node (sub-sector); exporter, importer	Sec. 11
(i, t, s), (i, j, t, s)	cell; directed dyad with reporter i and partner $j \neq i$	Secs. 2.2, 10
Normalisation and pillars		
x_{itsv}, r	raw variable; percent rank within comparison set g	Eq. (1)
ϕ_γ, γ	S-curve; curvature, $\gamma = 0.5$; $\phi_\gamma[\cdot]_g$ ranks within g	Eq. (1)
$\tilde{x}_{itsv}$, $\hat{x}_{itsv}$	theme index; after the missing-data rule	Eqs. (1), (2)
c_{itsk}, w_k^P	category score; weight of category k in pillar P	Eqs. (2), (3)
ES_{its}, EO_{its}	Energy Security and Economic Opportunity pillars, in $[0, 1]$	Eq. (3)
ι_{its}	imputed share of the cell's index weight; rankable if $\iota_{its} \leq 0.5$	Eq. (22)
Policy and Strategic Index		
POL_{its}, POL^*_{its}	Policy index; its S-curve across i's scored sectors	Eqs. (54), (56)
λ_s, g_t	stage weight; technology emissions weight (1 = cleanest)	Eqs. (4), (57)
SI_{its}	Strategic Index	Eq. (4)
Alignment and bilateral indices		
s_i, A_{ij}	position on the U.S.–China axis; dyadic alignment	Eqs. (50), (51)
FS_{ijts}, PO_{ijts}, DP_{jts}	Friendshore; Partnership Opportunity; Development Potential	Eqs. (66), (68), (69)
PSI_j	Partnership Strength Index	Eq. (72)
Allied Industrial Base		
C_n^{A}, C_n^{B}, C_n^{C}	coverage of the demand scope's traded demand after the shock, with existing relationships, with optimized trade	Eq. (6)
f_{em}, a_e, κ	flow from exporter e to importer m; available supply; maximum supplier share	App. C
HHI	Herfindahl–Hirschman index of supply	Sec. 11

Notes: The axis position s_i carries an economy subscript and the stage s none. The policy components x^v_{its} of Section 9 are distinct from the raw variable x_{itsv}, and the AIB node n from the count n_g of equation (1); Appendix C defines the remaining symbols of the AIB programs locally. Later sections introduce further symbols where they are needed.

3 Data

The indices combine public statistical releases, licensed commercial datasets and a few project-authored tables. Appendix B lists every source with its publisher, coverage and release, Appendix A every variable built from it, and Online Appendix OA.1 the rule that selects a release, the harmonisation of economy names and the years each source covers.

3.1 Sources by pillar

Table 4 groups the sources by what they measure. Most report economies, but some report the world (commodity prices, demand projections, technology readiness) or a few regions (manufacturing capacity, relative equipment costs); such a variable shifts a pair's level without ranking economies within it. Coverage ranges from about two hundred economies for trade and energy statistics to a few dozen for levelised costs, a gap that the missing-data rules of Section 4.3 bridge.

Energy security. The Statistical Review of World Energy (Energy Institute, 2026), 2026 edition with data to 2025, supplies consumption per capita and its growth, the fuel balances behind energy imports, mineral production and the proved reserves of oil, gas and coal, which the Review holds at end-2020. Fossil production that the Review counts only in a regional residual is taken from the U.S. Energy Information Administration (U.S. Energy Information Administration, 2026), in the Review's units and paired with consumption of the same year, as an observation (Estonian coal, where the Review counts oil shale, stays missing). Critical-mineral reserves at end-2025 (cobalt, lithium, graphite, rare earths, copper, manganese, nickel, zinc and the platinum-group metals) come from the USGS Mineral Commodity Summaries 2026 (U.S. Geological Survey, 2026), with the erratum that puts Brazil's rare-earth reserves at 11 Mt; holders listed without a figure ("NA", "W", "s") count as zero in the technology roll-ups. Nuclear Upstream is scored on the OECD-NEA/IAEA Red Book (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026): identified recoverable resources below USD 260/kgU at 1 January 2025 (59 economies) and mine production in 2019–2024 (18 producers in 2024), with economies absent from the tables recorded as zero. The IEA Critical Minerals Dataset (International Energy Agency, 2026a) provides mining (Upstream) and refining (Midstream) supply by economy and the clean-technology demand that weights each mineral within a technology. Midstream capacity shares come from IEA Energy Technology Perspectives (International Energy Agency, 2024), taken over the world total including the source's "Other" row. Its 2035 announced-capacity shares are regional for Europe, so every EU member carries the EU's share (0.15 in Wind, 0.11 in Batteries, 0.24 in Green Hydrogen and 0.00 in Solar Midstream) in the foreign-dependency and market-share variables, which therefore do not separate the members. Commodity prices (IMF Primary Commodity Price System, International Monetary Fund, 2026b), clean-technology investment (Clean Investment Monitor, Rhodium Group and MIT Center for Energy and Environmental Policy Research, 2026) and three geospatial resource-potential datasets complete the pillar.

Table 4: Source families, levels of observation and what they feed

Family	Sources	Level	Feeds
Energy statistics	EI Statistical Review 2026; EIA International Energy Statistics (fuel production EI does not report)	Economy	ES: energy access, consumption, energy imports, reserves (fossil), production (minerals). EO: energy access, production
Reserves and uranium	USGS Mineral Commodity Summaries 2026; OECD-NEA/IAEA Red Book (Uranium 2026); EI proved reserves	Economy	ES: reserves, production (uranium). EO: production (uranium). Coalition supplier test
Trade	UN Comtrade all-reporter dyads (2020, 2024) and their World totals; Atlas of Economic Complexity (HS92); Comtrade critical-minerals extracts	Economy; dyad	ES: trade, minerals trade. EO: trade. Friendshore, Partnership Opportunity, AIB flows
Minerals and manufacturing	IEA Critical Minerals Dataset 2026; IEA ETP 2024 capacity shares; IEA EV regional data	Economy; 5–6 regions	ES and EO: foreign dependency, production; mineral demand weights
Demand and technology	IEA WEO 2025; IEA Global EV Outlook 2026; BNEF New Energy Outlook 2024 and Supply Chains 2025; BCG market sizing; IEA Clean Energy Technology Guide	World; region; United States	ES: consumption. EO: consumption, technology demand, technological readiness
Costs and prices	BNEF LCOE; IEA relative costs; ILOSTAT earnings; IMF lending rates, producer prices and commodity prices	Economy; region; world	ES: energy prices. EO: cost competitiveness, energy prices
Potential and investment	Global Solar and Wind Atlases; geothermal potentials; Clean Investment Monitor	Economy	ES: reserves (downstream). ES and EO: investment
Policy	IEA Policies and Measures; Climate Action Tracker; IPCC lifecycle emissions; GTA NIPO (robustness only)	Economy; technology	Policy index; technology weight of the SI
Bilateral and alignment	IMF Direct Investment Positions; CM-FDI projects; WDI; Doing Business; OECD CRS; UNGA ideal points; agreement memberships	Dyad; economy	PSI components; blocs, coalition

Notes: ES = Energy Security; EO = Economic Opportunity; SI = Strategic Index; PSI = Partnership Strength Index. A source reported for a region or for the world is copied to the economies it covers by the theme that reads it. Appendix B gives publishers, coverage and releases; Appendix A the variables.

Economic opportunity. Export capability rests on the Growth Lab's reconciled HS92 data underlying the Atlas of Economic Complexity (The Growth Lab at Harvard University, 2019; Hausmann et al., 2014), newest year 2023, and on the 2024 Comtrade exports of Section 3.3. Demand comes from the IEA World Energy Outlook 2025 and Global EV Outlook 2026 (International Energy Agency, 2025b, 2026d), BloombergNEF's New Energy Outlook 2024 (BloombergNEF, 2024) and Supply Chains 2025 workbook, and a Boston Consulting Group sizing of the U.S. addressable market. Costs combine BloombergNEF levelised costs, IEA relative equipment costs, ILOSTAT earnings, IMF lending rates (placeholder zero readings dropped) and producer prices. The BloombergNEF and BCG inputs are licensed, which prevents a fully public replication of this pillar.

Technology readiness by stage. The IEA Clean Energy Technology Guide (International Energy Agency, 2026c) rates technology designs and components on an eleven-point readiness scale. Ordered rules assign each item to a technology and a stage or classify it as out of scope: 253 of the 634 items of the 2026 release map to a headline technology. A cell's readiness is computed from the items of its own stage; a stage without an item, 10 of the 33 cells, takes the technology-wide value. Readiness has no country dimension and is copied to every economy as an observation.

Policy. The Policy index combines the IEA Policies and Measures database (International Energy Agency, 2026e) (export of 22 January 2026), weight 3, and the Climate Action Tracker ratings (Climate Action Tracker, 2026) (39 countries and the EU, whose rating its unrated members take), weight 2. IEA PAMS is required and CAT added where it rates the country: 215 economies are scored, 65 on both and 150 on IEA PAMS alone (Section 9). The New Industrial Policy Observatory of Global Trade Alert (Global Trade Alert, 2026) enters only a robustness variant (Section 12). The technology weight of the Strategic Index uses the IPCC lifecycle-emission medians (Schlömer et al., 2014).

Bilateral, alignment and coalition inputs. Outward direct-investment positions come from the IMF Direct Investment Positions dataset. Positions with 16 conduit financial centres, the ten pass-through economies identified by Damgaard et al. (2024) and six offshore centres (Appendix A), are treated as unobserved on either side of the dyad. In battery, electric-vehicle, solar and wind manufacturing, the investment tie and the Chinese-parent exposure of Friendshore come instead from the Cleantech Manufacturing FDI dataset (Bandara and Net Zero Industrial Policy Lab, 2026), of whose 1,042 cross-border projects 905 qualify. Development potential uses the World Development Indicators (World Bank, 2026), the 2019 Doing Business scores (World Bank, 2020; World Bank Group, 2021) and OECD aid data. Geopolitical alignment uses the all-votes UN General Assembly ideal points of Bailey et al. (2017) (Dataverse V39, Voeten, 2009), averaged over sessions 74–78 (2019–2023), and coalition membership a project-authored list of U.S. free-trade agreements, IPEF, the Minerals Security Partnership, the G7 and NATO compiled from the official lists (Section 8).

3.2 The HS6 product crosswalk

Trade enters through baskets of six-digit Harmonized System (HS6) products, one per technology–stage pair, defined in one version-controlled table (`data/reference/energy_hs6_master.csv`) from which every trade and bilateral file is generated. With H_{ts} the codes in the basket of (t, s) and x_{ih} economy i's exports of product h, basket exports are

$$X_{its} = \sum_{h \in H_{ts}} x_{ih}, \tag{7}$$

and imports, world totals and bilateral flows are aggregated in the same way. Ores, concentrates, slag and scrap are Upstream, processed materials and components Midstream; Downstream activity is not a traded-goods stage.

The basket review. In October 2026 every code was tested for dominant use: it stays in a technology's basket only if that technology is a main use of the product. Ninety-two basket rows touching 69 codes failed (47 codes left every basket); each stays in the master with its reason. The crosswalk now holds 259 codes in 415 basket rows (298 in 490 before): 242 of the current nomenclature and 17 legacy codes that bridge the HS92 Atlas panels. The exclusions carried 92 percent of the pre-review coal Midstream basket's trade, 69 percent of gas Midstream and 89 percent of batteries Upstream, whose copper ores now belong to the grid (Table 5). Electric Grid Upstream held only electrical energy (HS 2716.00), which made net power exporters the grid's leading suppliers; it now holds seven copper and aluminium inputs, from ores and bauxite to cathodes and unwrought aluminium, so electricity is outside every basket. Switching and routing apparatus (HS 8517.62), 32 percent of the pre-review grid Midstream basket, is telecommunication equipment and left it.

Upstream baskets. Five Upstream baskets are new: Electric Vehicles (the battery-mineral ores and the rare earths of permanent magnets), Wind (rare earths), Nuclear (uranium ores and natural uranium compounds, the heading of most yellowcake, moved from Midstream), Solar (silicon metal) and Semiconductors (gallium, germanium and indium, carried for description only). The four that are scored trade USD 3.0 billion (wind) to 21.3 billion (electric vehicles) in 2024. With them, 18 of the 22 scored Upstream and Midstream pairs have a basket; only Geothermal and Green Hydrogen have none.

A many-to-many mapping. The baskets do not partition the product space: 105 codes (41 percent) belong to more than one basket, 63 to two, 33 to three and 9, the transformer, switchgear and cable headings, to four, since a power cable is an input to every technology that connects to the grid. Technology totals are therefore not additive, and the trade variables of technologies that share codes are mechanically correlated.

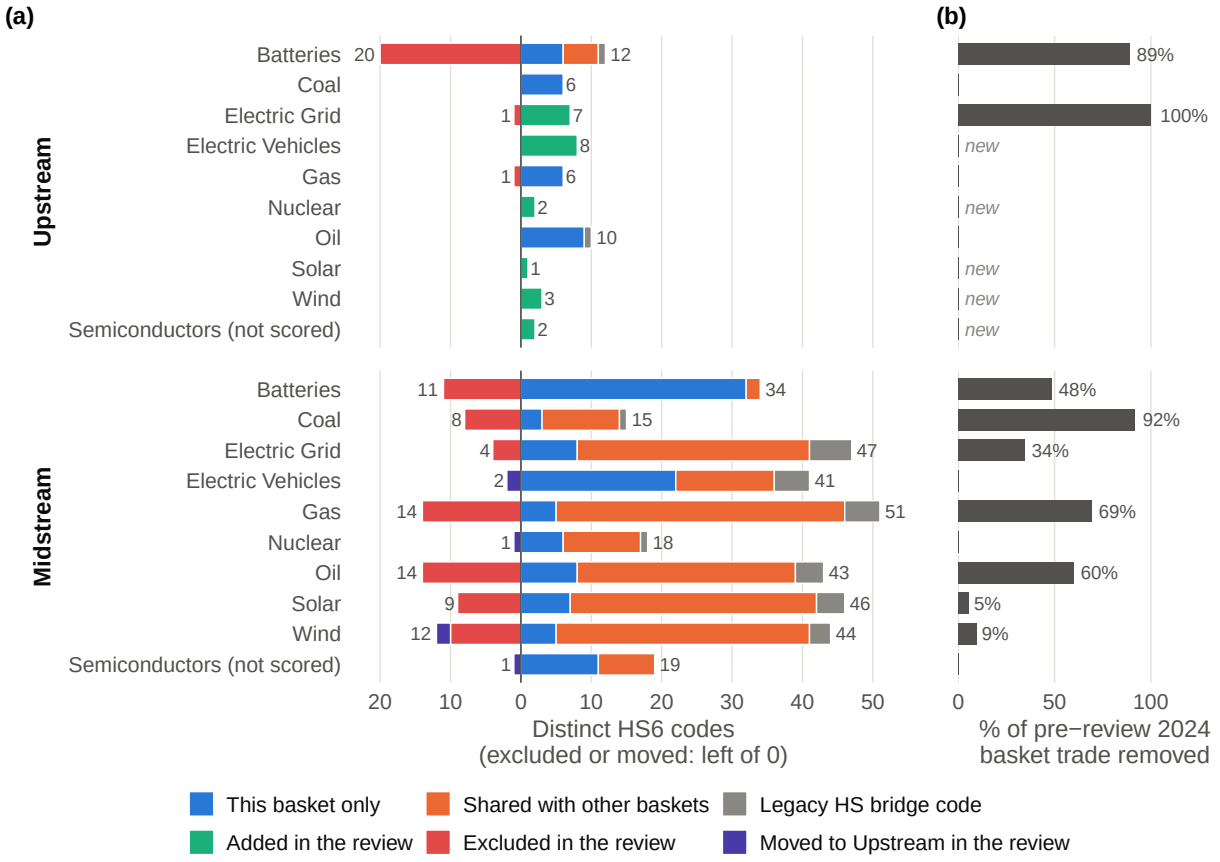

Figure 2: The HS6 baskets after the October 2026 review. Panel (a): distinct HS6 codes in each technology–stage basket, split into codes of that basket only, current codes shared with at least one other basket (the many-to-many part of the mapping), legacy HS bridge codes, and codes added by the review (codes moved from a technology's midstream basket count as added to its upstream basket); left of zero, the codes the review excluded from the basket and the codes it moved to the upstream stage. Panel (b): share of the pre-review basket's 2024 trade value carried by the excluded codes; "new" marks a basket the review created. Trade is the reconciled all-reporter Comtrade matrix (the importer's declaration, else the exporter's declaration $\times 1.06$), summed over exporter–importer pairs; a code in several baskets counts in each. Green hydrogen, geothermal and the downstream stage have no basket; semiconductors are carried in the master but not scored. Source: `data/reference/energy_hs6_master.csv`, `data/raw/comtrade_energy_dyads_all.csv`; `scripts/paper/fig_hs6_crosswalk.R`.

Table 5: HS6 baskets by technology and stage after the October 2026 basket review

		Codes in the basket				Review			Basket trade, 2024	
Technology	Stage	All	Legacy	Shared	Sub-sectors	Added	Moved	Excluded	USD bn	% removed
Batteries	Upstream	12	1	5	2	0	0	20	21.2	88.8
	Midstream	34	0	2	9	0	0	11	202.7	48.4
Coal	Upstream	6	0	0	2	0	0	0	192.5	0.0
	Midstream	15	1	12	3	0	0	8	20.5	91.9
Electric Grid	Upstream	7	0	0	3	7	0	1	321.0	100.0
	Midstream	47	6	36	12	0	0	4	449.6	34.3
Electric Vehicles	Upstream	8	0	8	8	8	0	0	21.3	new
	Midstream	41	5	17	7	0	2	0	1,003.2	0.0
Gas	Upstream	6	0	0	4	0	0	1	445.3	0.4
	Midstream	51	5	46	2	0	0	14	151.6	69.1
Nuclear	Upstream	2	0	0	2	2	0	0	11.4	new
	Midstream	18	1	12	3	0	1	0	24.6	0.0
Oil	Upstream	10	1	0	5	0	0	0	2,211.0	0.0
	Midstream	43	4	35	7	0	0	14	127.1	59.8
Solar	Upstream	1	0	0	1	1	0	0	3.8	new
	Midstream	46	4	38	9	0	0	9	711.5	5.5
Wind	Upstream	3	0	3	3	3	0	0	3.0	new
	Midstream	44	3	39	8	0	2	10	409.5	9.4
Semiconductors[a]	Upstream	2	1	0	1	2	0	0	1.1	new
	Midstream	19	0	8	8	0	1	0	1,348.1	0.0
Distinct codes		259	17	105	92	20	4	69		

Notes: Distinct HS6 codes in each technology–stage basket of `data/reference/energy_hs6_master.csv` after the review. "Legacy" codes are bridge codes of older HS revisions whose successors are all in the basket; "Shared" counts the codes that also belong to at least one other basket. "Excluded" counts the codes the review removed from the basket because the technology is not a dominant use of the product, and "Added" the codes it added (the copper and aluminium inputs that replace electrical energy, HS 2716.00, in electric-grid Upstream, and the Upstream baskets of electric vehicles, solar, wind, nuclear and semiconductors, which had none); "Moved" counts the codes it moved from a technology's Midstream to its Upstream basket (rare-earth compounds and metals, natural uranium compounds, unwrought gallium, germanium and indium), which count as added there, since a code sits in one stage of a technology; the rows stay in the master with the reason. Basket trade is the 2024 value in the reconciled all-reporter Comtrade matrix (the importer's declaration, else the exporter's mirror declaration × 1.06), summed over exporter–importer pairs; "% removed" is the share of the pre-review basket's value carried by the excluded codes (moved codes are not removals; "new" marks a basket the review created). A code in several baskets counts in each, so neither codes nor trade values add across rows. Green hydrogen, geothermal and the Downstream stage have no basket.

[a] Carried in the master; not a scored technology.

3.3 Bilateral trade and the trade themes

Bilateral flows come from an all-reporter pull of UN Comtrade (United Nations Statistics Division, 2026) for the endpoint years 2020 and 2024: 173 economies report in at least one year (168 in 2020; 142 for exports and 143 for imports in 2024), and 208 appear as reporter or partner. Comtrade records Taiwan as "Other Asia, n.e.s." (partner code S19), which is mapped to Taiwan's own code. Let $M^{\text{rep}}_{ji,h}$ be importer j's declared imports of product h from i and $X^{\text{rep}}_{ij,h}$ exporter i's declared exports to j. The flow in a cell is

$$F_{ij,ts} = \begin{cases} \sum_{h \in H_{ts}} M^{\text{rep}}_{ji,h} & \text{if } j \text{ reports imports in the cell that year,} \\ 1.06 \sum_{h \in H_{ts}} X^{\text{rep}}_{ij,h} & \text{otherwise, if } i \text{ reports exports to } j, \end{cases} \tag{8}$$

and unobserved otherwise; 1.06 is the IMF's conventional ratio of CIF import to FOB export values. Of the 701,214 exporter–importer–technology–stage cells observed in 2024, 22 percent are mirror values, but only 13 percent of the cells with positive trade and 4 percent of the value, because large traders report. Thirty importers that reported in 2020 did not in 2024, among them Russia, Iran, the United Arab Emirates and Viet Nam, and 65 of the 208 importers enter the 2024 matrix only through their partners' declarations, which omits their imports from exporters that do not report either.

The country-level trade themes read a file of exports and imports by reporter and code rebuilt from the World rows of the same pull: 142 exporting and 143 importing reporters in 2024 and every current-nomenclature basket code, including Qatar's exports of liquefied natural gas (USD 56.9 billion), which the earlier extract omitted. Hong Kong is left out of the Comtrade export measures (export size, revealed comparative advantage (Balassa, 1965) and export concentration) because its exports are mostly re-exports that the producers' own exports already count; it keeps its Atlas-based variables, and the bilateral matrix is not filtered. The export-concentration index is ranked across the cells of the eleven headline technologies only. Critical-minerals trade uses separate 2024 Comtrade extracts (130 import and 128 export reporters); the 2025 extracts, with three reporters, fall below the coverage floor of the release rule (Online Appendix OA.1).

3.4 Economies, coverage and rankability

Every economy name in every source is mapped to one canonical name per ISO3 code before anything is ranked, and world, regional, residual and historical aggregates are dropped. The headline pillars then cover 219 economies, each with its own ISO3 code, of which 195 are sovereign states (the 193 members of the United Nations, Kosovo and Taiwan) and 24 are territories, special administrative regions or the West Bank and Gaza; the same 219 economies (195 sovereign states and 24 territories) have an EO score, so the two pillars share one universe. Taiwan, which the World Bank's country table does not list, is carried as an economy throughout, including the trade themes and the bilateral matrix; it has an ES value in 28 headline cells and an EO value in 33. The pillars score 6,232 ES and 7,131 EO country–technology–stage cells in 30 and 33 headline pairs. In the alignment data

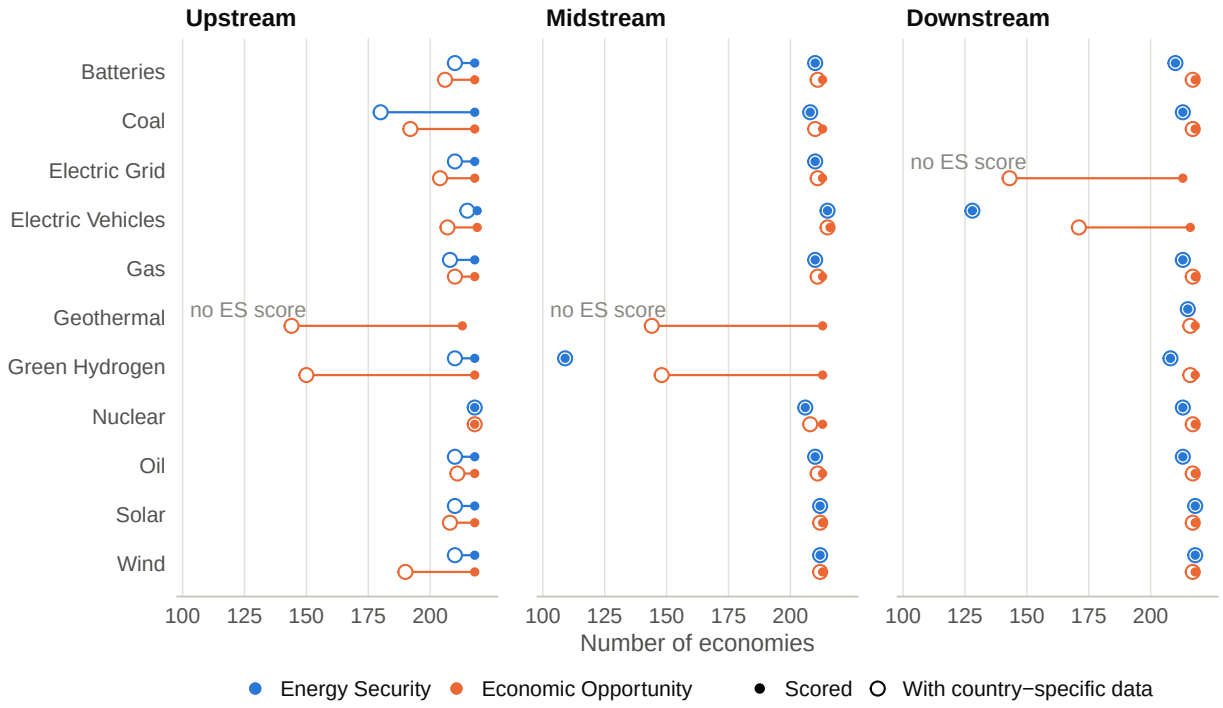

Figure 3: Economies scored and economies with country-specific data, by technology–stage pair. Filled dots: the number of economies with a pillar value in the pair. Hollow circles: the number of those economies for which at least one positively weighted, non-imputed component is country-specific, that is, takes at least two distinct observed values across the economies of the pair. World-level series copied to every economy, such as commodity-price volatility, world export concentration and technology readiness, do not count as country-specific. The segment between the two marks is the number of economies whose value rests only on imputed components and world-level series; where the two counts coincide the marks appear as a ringed dot. "No ES score" marks the pairs without an ES value. Every pair has status ok (no pair is constant or unscored). The axis starts at 100 economies. Sample: the eleven headline technologies. Source: variable contributions and pillar diagnostics in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_method.R`.

the 193 economies that vote in the General Assembly have an ideal point; the other economies are treated as Section 8 describes.

The grids span almost the whole universe at every stage, but their width is set by the most widely distributed theme of each pair. Figure 3 separates economies scored from economies with country-specific data. In ES the two differ only upstream, where a commodity-price series copied to every economy sets the grid: by 4 economies in Electric Vehicles to 38 in Coal, and not at all in Nuclear once absence from the uranium registers is recorded as zero. In EO the gap is largest in Electric Grid downstream (143 of 213 economies with country-specific data). Territories rest more heavily on imputation (mean imputed weight 0.48 of a territory's ES cell against 0.29 for a sovereign state; 0.67 against 0.40 in EO).

Because coverage is uneven, every cell is scored but not every cell is ranked: a cell enters a ranking, a top-N list, the Strategic Index or the partner rankings only if the economy is sovereign and at most half of its index weight rests on imputed components (Section 4.7). The rule keeps

4,163 of the 6,232 ES cells and 4,301 of the 7,131 EO cells. Each component is taken at the latest year its source reports, so a cell can combine observations from 2023 to 2025 with projections to 2035 and, in ES reserves, end-2020 fossil stocks (Section 4.2).

4 Index construction: normalisation, imputation and aggregation

Construction has two layers. In the *theme layer* each source's builder orients its raw metrics (higher means more security or more opportunity) and maps them to the unit interval by a rank-based S-curve. In the *aggregation layer* the latest observation of each variable is selected, gaps are filled by explicit rules, and variables are averaged into categories and categories into pillars; nothing is re-ranked there. Online Appendix OA.2 gives the construction algorithm, the derivations and further diagnostics.

4.1 Percent ranks and the median S-curve

Let $x = (x_a)_{a \in A}$ be the values of an oriented raw variable over a comparison set A with n non-missing values. The percent rank and the normalised value, restating equation (1), are

$$r_a = \begin{cases} \dfrac{\operatorname{rank}(x_a) - 1}{n - 1}, & n \geq 2, \\ 0, & n = 1, \end{cases} \tag{9}$$

$$\phi_\gamma(r_a) = \frac{r_a^\gamma}{r_a^\gamma + (1 - r_a)^\gamma}, \qquad \gamma = 0.5, \tag{10}$$

with ties given the average of the ranks they occupy; a missing value stays missing. We write $\phi_\gamma[x]_g$ for the transform taken separately within each cell of a grouping g. The function is the one-parameter probability-weighting function of Karmarkar (1978) applied to ranks rather than probabilities, the unit-elevation member of the linear-in-log-odds family of Gonzalez and Wu (1999):

$$\operatorname{logit} \phi_\gamma(r) = \gamma \operatorname{logit} r. \tag{11}$$

The curve is median-centred ($\phi_\gamma(0) = 0$, $\phi_\gamma(1/2) = 1/2$, $\phi_\gamma(1) = 1$ for every γ), ordinal, hence insensitive to outliers (Conover and Iman, 1981), and symmetric, $\phi_\gamma(1 - r) = 1 - \phi_\gamma(r)$. With $\gamma < 1$ it is an inverse S: the bottom and top tenths of a comparison set occupy $[0, 0.25]$ and $[0.75, 1]$, while the middle half is compressed into an interval of width 0.27 (0.5 under the percent rank). The choice $\gamma = 0.5$ is a stated value judgement: moving into the lead of a distribution, or out of its bottom, is worth more than an equal move in rank within the middle, so dominance and absence, the distinctions most relevant to supply security, are set apart (Figure 4). Section 12 varies γ.

Zero anchor, comparison sets and cardinal inputs. Ranked with positive values, tied zeros would score mid-table (0.41 for $(0, 0, 0, 5)$), above an economy a register omits. Measures of activity

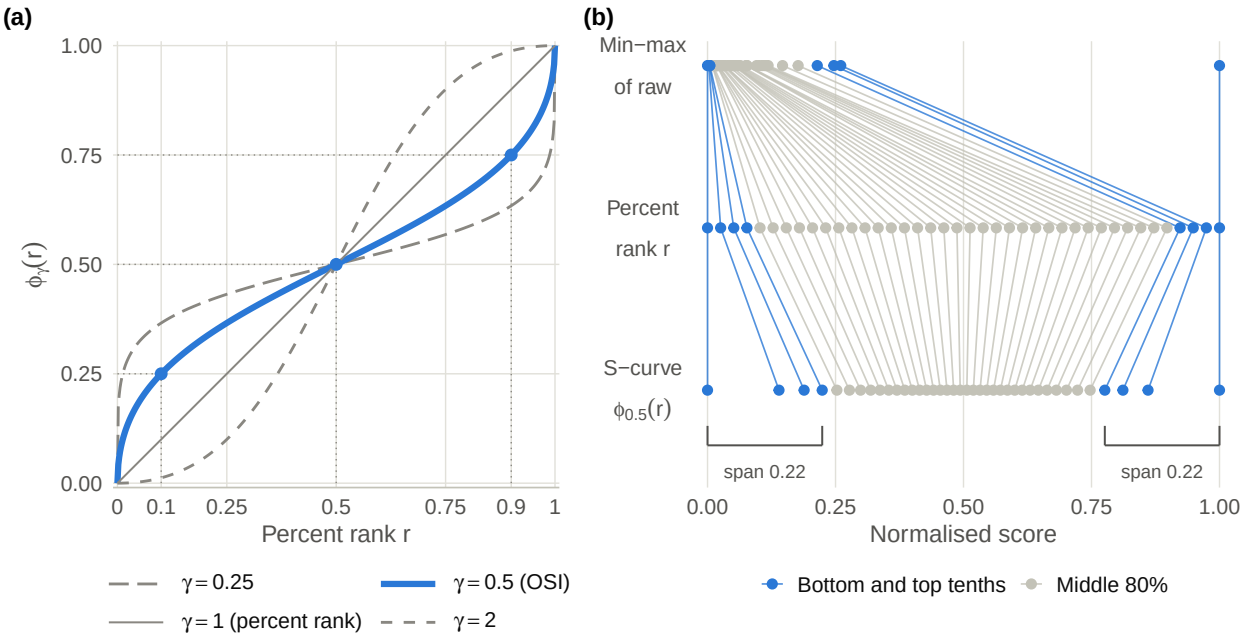

Figure 4: The median-centred S-curve. Panel (a): $\phi_\gamma(r) = r^\gamma/[r^\gamma + (1-r)^\gamma]$ against the percent rank r for $\gamma \in \{0.25, 0.5, 1, 2\}$. The highlighted curve is $\gamma = 0.5$, the value used for every component of the indices, and the marked points are $\phi_\gamma(0.1) = 0.25$, $\phi_\gamma(0.5) = 0.5$ and $\phi_\gamma(0.9) = 0.75$; $\gamma = 1$ is the percent rank itself. Panel (b): 40 draws of a right-skewed variable (lognormal, log-mean 0, log-standard deviation 1, fixed seed) under three normalisations, with each observation joined across the rows: a min-max rescaling of the raw value, the percent rank r of equation (9), and the S-curved index of equation (10) computed by the pipeline's own function. The four lowest and four highest observations are highlighted, and the brackets give the span the S-curve assigns to each group. No pipeline data are used. Source: `scripts/paper/fig_scurve.R`.

or endowment (investment, capacity, mineral supply and export shares, reserves and production roll-ups) therefore use an anchored form, with m positive values and rank^+ the average-tie rank among them:

$$\phi^0_\gamma[x](a) = \begin{cases} 0, & x_a = 0, \\ \phi_\gamma(\text{rank}^+(x_a)/m), & x_a > 0. \end{cases} \tag{12}$$

The comparison set is usually the economies observed in a pair; world-level series are ranked across technologies, pairs or minerals and copied to every economy. Index values are positions in a cross-section, not levels. Three EO inputs are cardinal transformations instead (Section 6).

4.2 Latest-year selection

For every economy, technology, stage, category, variable and theme the aggregation layer keeps the latest year present,

$$y^*_{itskvh} = \max\{y : \text{ a row } (i,t,s,k,v,h,y) \text{ exists}\}, \qquad x^h_{itskv} \equiv x^h_{itskv,y^*_{itskvh}}, \tag{13}$$

before imputation. It is a rule about the freshest information on each quantity, not a common reference year: 60 percent of the ES cells and 92 percent of the EO cells of the eleven headline technologies combine components from more than one year, with at most 3 distinct years in an ES cell and 6 in an EO cell (4 once the projection horizons after 2026 of the outlook series are set aside).

4.3 Missing data: observed-only imputation

Each pair's table is completed to the product of the economies in any of the pillar's rows for the pair and the component groups $g = (t,s,k,v,h)$ occurring there. The ES grids span 219, 215 and 219 economies at the three stages and the EO grids 219, 216 and 219. With O_g the economies observed in g and m_g the rule of the emitting theme (Table 6),

$$\hat{x}_{ig} = \begin{cases} x_{ig}, & i \in O_g, \\ 0, & i \notin O_g,\ |O_g| \geq 1,\ m_g = \text{zero}, \\ \bar{x}_g = \dfrac{1}{|O_g|}\displaystyle\sum_{j \in O_g} x_{jg}, & i \notin O_g,\ |O_g| \geq 1,\ m_g = \text{global average}, \\ \text{missing}, & \text{otherwise}. \end{cases} \tag{14}$$

Imputation uses observed values only: a fill is computed from the economies observed in the group, never from other fills, and a group observed for no economy stays missing. The zero rule, for registers of holders, producers and investors, places an unlisted economy at the bottom, level with an observed zero: absence from a complete register means none recorded, and leaving it missing would reward the absence of an endowment. The global-average rule, for attributes every economy

has in some degree, places it near 1/2, so that "not measured" is not read as "worst". Every fill is flagged and carried into the decompositions.

4.4 Category scores and available-case aggregation

A category is scored by a configured overall variable, the unweighted mean of its components present in the cell (a component reported by several themes is first averaged across them),

$$c_{kits} = \frac{1}{|\mathcal{V}^*_{kits}|} \sum_{v \in \mathcal{V}^*_{kits}} \tilde{x}_{itsv}, \qquad \mathcal{V}^*_{kits} = \{v \in \mathcal{V}_k : \ \tilde{x}_{itsv} \text{ not missing}\}, \tag{15}$$

which is c_{itsk} of equation (2) with the category index written first. With K_{its} the categories observed in the cell and w_k the nominal weights of Table 7, the pillar is the available-case weighted mean

$$\mathrm{ES}_{its} = \frac{\sum_{k \in K_{its}} w_k \, c_{kits}}{\sum_{k \in K_{its}} w_k} = \sum_{k \in K_{its}} \omega_{kits} \, c_{kits}, \tag{16}$$

$$\omega_{kits} = \begin{cases} w_k / \sum_{k' \in K_{its}} w_{k'}, & k \in K_{its}, \\ 0, & k \notin K_{its}, \end{cases} \tag{17}$$

and identically for EO_{its}. The rule is equivalent to imputing an unobserved category at the cell's own mean; zero-filling would instead penalise coverage rather than performance. The pillar is a weighted mean of S-curved scores, not itself a percentile.

Composition differs across pairs, not within them. Because every theme but the levelised-cost theme carries a rule, all scored economies share one category set in all of the 30 ES pairs and all of the 33 EO pairs (Online Appendix OA.2): within-pair comparisons are comparisons of one construct. Across pairs a cell has between 1 and 7 observed categories in ES (median 3; 21 percent of cells have a single category) and between 2 and 7 in EO (median 6). The effective weights therefore depart far from the nominal ones (Figure 5): ES Trade, nominally 0.095, carries 0.59 at the midstream stage and Consumption (0.119) 0.49 downstream, the gap between nominal and effective importance that Paruolo et al. (2013) stress. A category constant within a pair, such as Energy Prices or Technological Readiness, makes the pillar an affine function of the pillar without it,

$$\mathrm{ES}_{its} = \omega_{kts} \, \bar{c}_{kts} + (1 - \omega_{kts}) \, \mathrm{ES}^{(-k)}_{its}, \tag{18}$$

which shifts levels without reordering economies and matters only where levels are compared across pairs, as in the Strategic Index (Section 9). The weights are normative (Decancq and Lugo, 2013); Section 12 varies them.

Table 6: Missing-data rules by theme

Theme	Category	ES	EO	Rationale
Panel A: registers of holders, producers and investors (zero rule)				
`critical_minerals_production`	Production	zero	–	Unlisted economy has no recorded mine output
`critical_minerals_processing`	Foreign Dependency	zero	–	Unlisted economy has no recorded supply share
`critical_minerals_trade`	Minerals Trade	zero	–	No recorded exports of the mineral
`reserves`	Reserves	zero	–	Reserve tables (USGS, EI, Red Book) list every holder
`investment_momentum`	Investment	zero	zero	Investment and capacity records; no record means none recorded
`market_share_manufacturing`	Foreign Dependency	–	zero	No recorded manufacturing share
Panel B: attributes every economy has (global-average rule)				
`energy_access_consumption`	Energy Access	avg	avg	Coverage gap
`energy_consumption`	Energy Access, Consumption	avg	avg	Coverage gap
`solar_pv_potential`	Reserves	avg	avg[a]	Every territory has some resource potential
`wind_potential`	Reserves	avg	avg[a]	As above
`geothermal_potential`	Reserves	avg	avg[a]	As above
`import_dependence`	Energy Imports	avg	–	Coverage gap
`foreign_dependency`	Foreign Dependency	avg	–	Fills economies outside the theme's roster
`trade_concentration`	Trade	avg	–	Coverage gap
`export_feasibility`	Trade	–	avg	Coverage gap
`energy_prices`	Energy Prices	avg	avg	World series; the mean is the common value
`future_demand`	Technology Demand	–	avg	Market-level outlooks
`overcapacity_premium`	Technology Demand	–	avg	Market-level outlooks
`technological_readiness`	Technological Readiness	–	avg	Technology-level value
`cost_competitiveness`	Cost Competitiveness	–	avg	Coverage gap
`production_depth_momentum`	Production	–	avg	Coverage gap
Panel C: no rule (missing values stay missing)				
`lcoe_competitiveness`	Cost Competitiveness	–	none	Uncovered markets scored on the other cost components

Notes: "zero" assigns the bottom of the index scale and "avg" the mean of the observed index values within the technology×stage×category×variable×theme group, equation (14); either rule applies only in groups where at least one economy is observed. "–": the theme is not an input to the pillar. Source: `config/missing_data.yml`.
[a] Inert: the potential themes supply only the Reserves category, which EO does not score.

Table 7: Nominal category weights

Energy Security			Economic Opportunity		
Category	w_k	Share	Category	w_k	Share
Foreign Dependency	6	0.143	Technology Demand	4	0.133
Production	6	0.143	Trade	3	0.100
Consumption	5	0.119	Production	3	0.100
Energy Imports	4	0.095	Energy Prices	3	0.100
Reserves	4	0.095	Investment	3	0.100
Trade	4	0.095	Energy Access	3	0.100
Minerals Trade	4	0.095	Foreign Dependency	3	0.100
Energy Access	4	0.095	Cost Competitiveness	3	0.100
Investment	3	0.071	Consumption	3	0.100
Energy Prices	2	0.048	Technological Readiness	2	0.067
Total	42	1.000	Total	30	1.000

Notes: Share is $w_k / \sum_{k'} w_{k'}$, the weight a category would receive in a cell in which all ten are observed; no cell observes all ten. The weight applied in a cell is ω_{kits} of equation (17). Source: `config/weights.yml`.

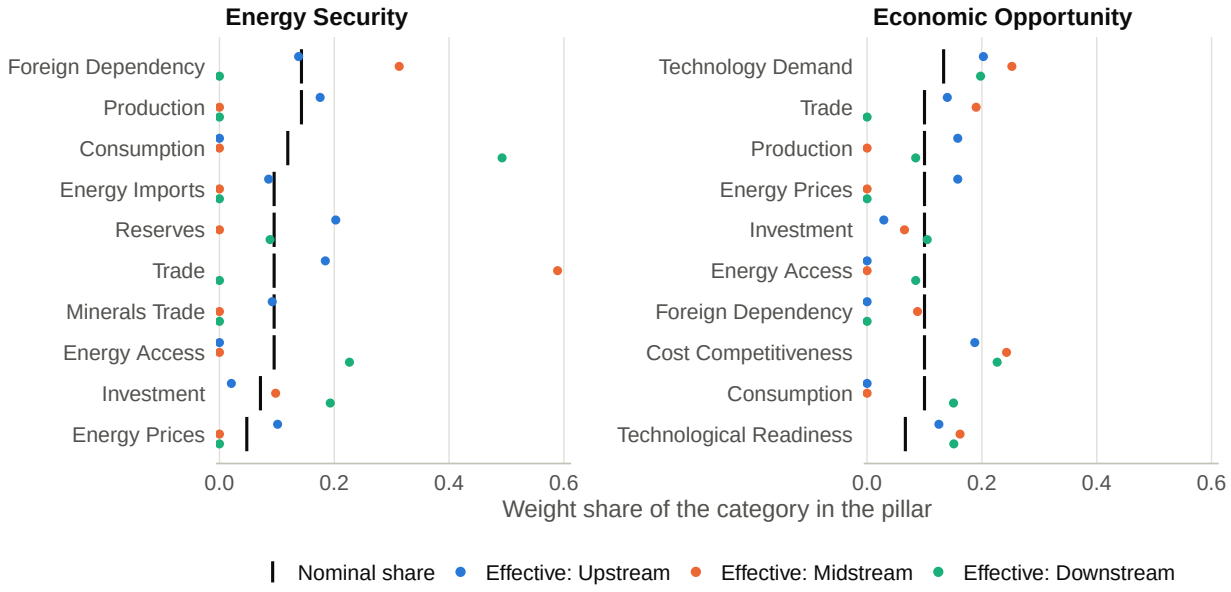

Figure 5: Nominal and effective category weights. Black ticks: nominal share $w_k / \sum_{k'} w_{k'}$ over the ten categories of the pillar (`config/weights.yml`; Table 7). Dots: mean effective weight ω_{kits} (equation (17)) over the scored cells of the eleven headline technologies at each stage, with $\omega_{kits} = 0$ where the category is not observed. A dot at zero marks a category that is never observed at that stage. The effective weights of a stage, like the nominal shares, sum to one over the categories. A dot to the right of the tick means that the available-case rule gives the category more weight than its nominal share. Cells: 2,181, 2,002 and 2,049 for ES and 2,394, 2,346 and 2,391 for EO (upstream, midstream, downstream). Source: category contributions in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_method.R`.

4.5 Exact decompositions

With $C_{kits} = \omega_{kits} c_{kits}$ and $\lambda_{vkits} = 1/|\mathcal{V}^*_{kits}|$ for a present component (0 otherwise), every pillar value decomposes exactly into category and variable contributions,

$$\mathrm{ES}_{its} = \sum_{k \in \mathcal{K}^P} C_{kits}, \qquad \sum_{k \in \mathcal{K}^P} \omega_{kits} = 1, \tag{19}$$

$$\mathrm{ES}_{its} = \sum_{k \in \mathcal{K}^P} \sum_{v \in \mathcal{V}_k} \underbrace{\omega_{kits}\, \lambda_{vkits}\, \tilde{x}_{itsv}}_{\text{contribution of } v}, \qquad \sum_{k} \sum_{v} \omega_{kits}\, \lambda_{vkits} = 1. \tag{20}$$

The largest absolute difference between the index and the sum of its contributions is exactly zero for the category decomposition and 1.1×10^{-16} for the variable decomposition, in both pillars (7,794 ES and 7,661 EO cells, all technologies), so the attributions of Sections 5 and 6 are exact.

4.6 The imputed weight share

The share of a cell's weight carried by imputed components is

$$\iota_{its} = \sum_{k} \sum_{v} \omega_{kits}\, \lambda_{vkits}\, \mathbf{1}\big[\tilde{x}_{itsv} \text{ imputed}\big] \in [0, 1], \tag{21}$$

counting zero and average fills alike; a world-level series copied to every economy counts as observed. Imputed components carry on average 31 percent of the weight of an ES cell and 43 percent of an EO cell (medians 0.26 and 0.44; Figure 6). The ES burden is heaviest upstream (0.41, against 0.23 and 0.27), where Reserves, zero-filled for economies absent from the registers, is imputed at 0.84; the EO burden is flat across stages (0.41, 0.44, 0.43). No ES cell and 24 EO cells (the Isle of Man 14, Puerto Rico 8, Liechtenstein 2) rest entirely on imputation. All 30 ES and 33 EO headline pairs vary across economies.

4.7 The rankability rule

Every cell the sources reach is scored and enters the decompositions, but a cell enters a cross-country ranking, a top-N list or the Strategic Index only if it is rankable,

$$R_{its} = \mathbf{1}\big[i \in \mathcal{I}^{\mathrm{sov}}\big]\ \mathbf{1}\big[\iota_{its} \le \tau\big], \qquad \tau = 0.5, \tag{22}$$

where $\mathcal{I}^{\mathrm{sov}}$ is the set of 195 sovereign states of the Correlates of War state-system list (Correlates of War Project, 2024) (the 193 UN members, Kosovo and Taiwan). The threshold reads as "observed data carry at least half of the cell's weight"; values are never altered, and the Partnership Strength Index applies the same rule to partners (Section 10).

Of the 6,232 headline ES cells, 4,163 (67 percent) are rankable, 607 belonging to territories and 1,462 to sovereign states over the threshold; in EO, 4,301 of 7,131 (60 percent), with 718 and 2,112 excluded (Figure 7). The rule bites hardest in upstream ES (52 percent rankable, against 70 and

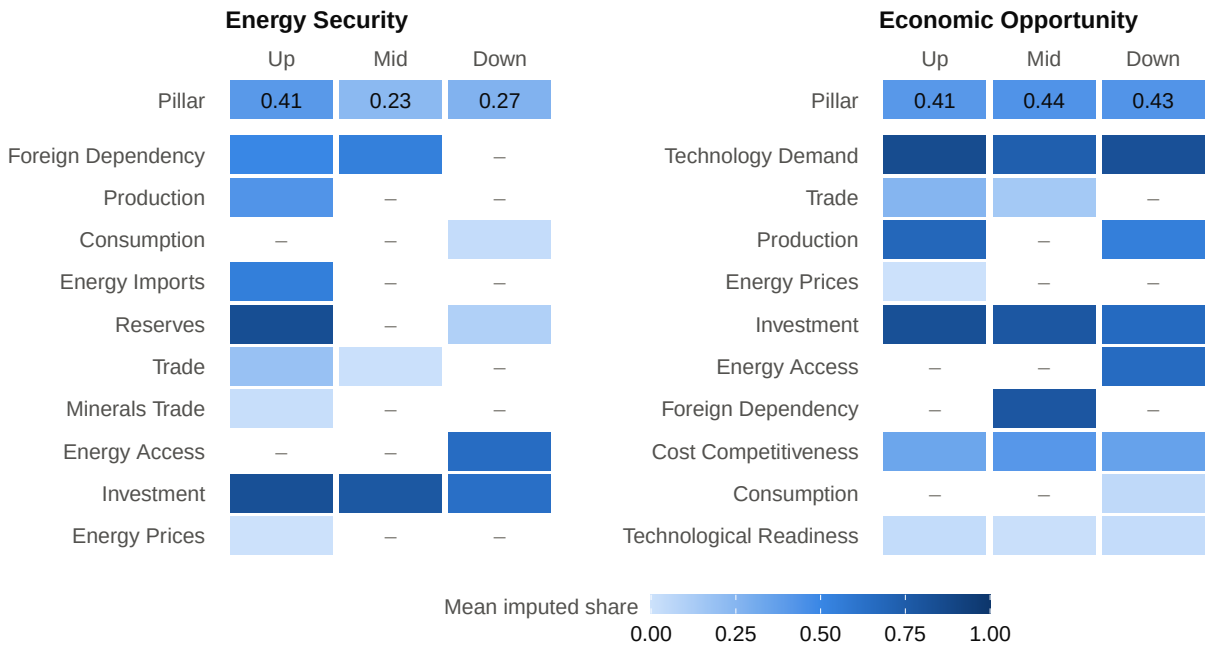

Figure 6: Imputation burden by category and stage. Category rows: the mean, over the headline cells in which the category is observed, of the share of the category score carried by imputed components, $\sum_v \lambda_{vkits} \mathbf{1}[\tilde{x}_{itsv}$ imputed]. Pillar row (with values): the mean imputed weight share ι_{its} of equation (21) over all scored cells of the stage, which weights the category rows by the effective weights. Dashes mark categories that are not observed at a stage. A component counts as imputed when a missing-data rule of Table 6 supplied it, zero fills included; world-level series copied to every economy count as observed. Online Appendix OA.2 tabulates the values. Source: variable contributions and pillar diagnostics in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_method.R`.

80), where the registers cover a minority of economies, and in midstream and downstream EO (56 and 55 percent, against 70). Every sovereign state keeps a rankable ES cell, but 17 keep no rankable EO cell (Liechtenstein, Monaco and fifteen small island and low-income states). The rule is not level-neutral: since absence from a register scores at the bottom, excluded cells lean insecure. Of the 5,854 candidate Strategic Index cells, the 3,154 kept have a mean security need $1 - \text{ES}$ of 0.58 and EO of 0.49, against 0.68 and 0.44 for those removed. The rule states what the data can support rather than correcting the index; Section 12 reports other thresholds.

What the construction does not do. The stages of a technology are scored independently, although disruptions propagate along supply chains (Carvalho et al., 2021); dependence across stages enters only where a variable encodes it, as the mineral-supply terms of foreign dependency do. Section 12 reports the test of vertical complementarities behind this choice. Imputation assigns one value per uncovered economy, so it understates the uncertainty of imputed cells.

5 The Energy Security Index

The Energy Security pillar ES_{its} asks how far economy i can rely on the supply of technology t at supply-chain stage s: of the minerals it is built from, of the materials, components and equipment that embody it, and of the energy it delivers. Following Cherp and Jewell (2014), security is the low vulnerability of vital energy systems, scored on the dimensions the measurement literature shares: domestic resources, dependence on imports and on few suppliers, price stability and access (Kruyt et al., 2009; Sovacool and Mukherjee, 2011; Winzer, 2012; Ang et al., 2015); in the terms of Cherp and Jewell (2011), sovereignty, resilience and robustness. Because the "fuel" of a clean technology is a bundle of minerals and manufactured inputs, the pillar borrows the supply-risk logic of the criticality literature (Graedel et al., 2012; Nassar et al., 2020; Kowalski and Legendre, 2023; International Energy Agency, 2025a) and the concentration index of Hirschman (1945). A higher score means a more secure position; the Strategic Index (Section 9) uses the need $1 - \text{ES}_{its}$.

5.1 Construction

Ten categories (Table 8, weights summing to 42) are combined by the rules of Section 4 into the available-case weighted mean of equation (16). Registers of holders, producers, exporters or investors carry the zero rule and the zero-anchored S-curve of equation (12), the other themes the global-average rule (Table 6). The category bundle, and with it the effective weights of equation (17), differs across pairs but is common to all economies within one. Mineral-level terms are aggregated to a technology with demand weights from the IEA Critical Minerals Dataset (International Energy Agency, 2026a), Stated Policies scenario:

$$w^{y}_{mt} = \frac{D^{y}_{mt}}{\sum_{t'} D^{y}_{mt'}}, \qquad \tilde{w}^{y}_{mt}(M) = \frac{w^{y}_{mt}}{\sum_{m' \in M} w^{y}_{m't}}, \qquad m \in M, \tag{23}$$

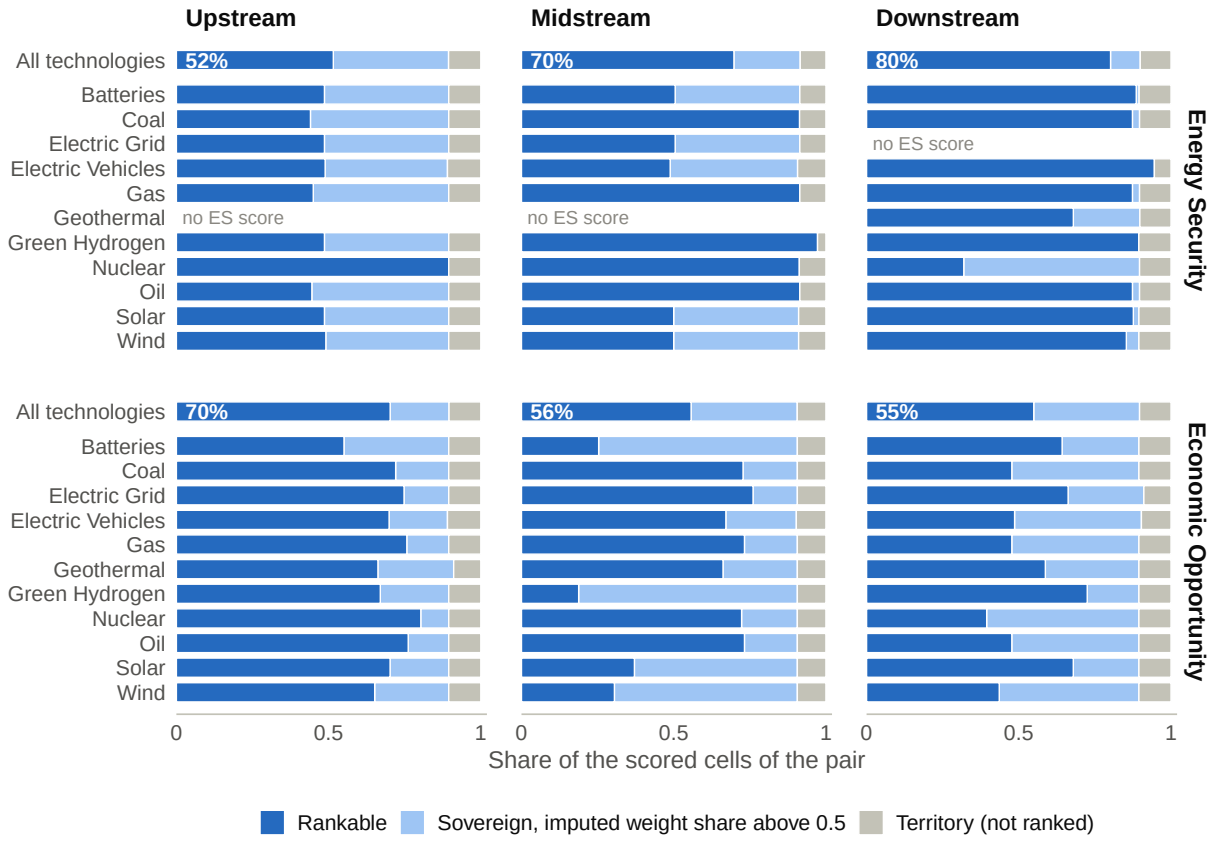

Figure 7: Rankability of the scored cells by technology–stage pair. Each bar divides the scored country–technology–stage cells of a pair into three exclusive groups: rankable cells (the economy is a sovereign state and the imputed weight share ι_{its} is at most $\tau = 0.5$); cells of sovereign states with $\iota_{its} > 0.5$; and cells of territories, special administrative regions and the West Bank and Gaza, which are scored but never ranked whatever their imputed share. The "All technologies" row pools the pairs of the stage, and its label gives the rankable share. Sovereignty follows the Correlates of War state-system list (195 states: the 193 members of the United Nations, Kosovo and Taiwan). "No ES score" marks the three pairs without an ES value. Sample: the eleven headline technologies, 6,232 ES and 7,131 EO cells; Online Appendix OA.2 gives the counts by stage. Source: `energy_security_index` and `economic_opportunity_index` in `data/processed/outputs/index_outputs.rds`; `config/rankability.yml`; `scripts/paper/fig_method.R`.

Table 8: Structure of the Energy Security pillar

Category (weight)	Stages: technologies	Components	Sources	Rule
Foreign Dependency (6)	Up, Mid: Bat, EV, Grid, H_2, Sol, Wind	own share and $1-$ HHI of mined (Up) or refined (Mid) mineral supply, 2025 and 2035; Mid: share of world manufacturing capacity (Bat, Sol, Wind), regional EV position (EV)	IEA Critical Minerals Dataset; IEA ETP; IEA Global EV Outlook	avg, zero
Energy Imports (4)	Up: Oil, Gas, Coal	production balance (EJ) and self-sufficiency	EI Statistical Review; EIA	avg
Reserves (4)	Up: all but Geo; Down: Sol, Wind, Geo	proved fossil reserves; demand-weighted mineral reserves; identified uranium resources; renewable resource potential	EI; USGS MCS 2026; Red Book; resource atlases	zero, avg
Trade (4)	Up, Mid: all but Geo, H_2	share of world basket exports; net basket imports/GDP; $1-$ world export HHI†	Atlas; UN Comtrade; WDI	avg
Minerals Trade (4)	Up: Bat, EV, Grid, H_2, Sol, Wind	demand-weighted share of world mineral exports; $1-$ HHI†	UN Comtrade	zero
Production (6)	Up: Bat, EV, Grid, H_2, Sol, Wind, Nuc	demand-weighted mine production; uranium mine output	EI; Red Book	zero
Energy Access (4)	Down: Coal, Oil, Gas, Sol, Wind, Nuc	energy supply per capita, level and growth	EI	avg
Consumption (5)	Down: all but EV, Grid	installed capacity per capita, level and growth to 2035	BNEF NEO 2024	avg
Energy Prices (2)	Up: all but Geo	commodity price volatility†	IMF PCPS	avg
Investment (3)	Up: Bat, EV; Mid: Bat, EV, Sol, Wind; Down: monitor technologies	investment, momentum, operating and pipeline capacity	Clean Investment Monitor	zero

Notes: Weights from `config/weights.yml`, renormalized over the observed categories of each cell (equation (16)). Up, Mid, Down: upstream, midstream, downstream; Bat batteries, EV electric vehicles, Grid electric grid, H_2 green hydrogen, Sol solar, Nuc nuclear, Geo geothermal. †Constant across economies within a pair. Rule: missing-data rule of the themes (avg: global average; zero). Variables in Appendix A.

where D^y_{mt} is the demand for mineral m from application t in the base year $y_0 = 2025$ or the horizon $y_1 = 2035$, and $\tilde{w}$ renormalizes over the set M of minerals a category observes: t's share of the mineral's clean-energy demand.

5.2 Categories

Foreign Dependency. The core component is the economy's position in the IEA's mined (upstream) and refined (midstream) supply of copper, cobalt, lithium, nickel, graphite and the magnet rare earths. With Q^y_{ims} the supply of mineral m by economy i at stage s,

$$\sigma^y_{ims} = \frac{Q^y_{ims}}{\sum_j Q^y_{jms}}, \qquad \mathrm{HHI}^y_{ms} = \sum_j \left(\sigma^y_{jms}\right)^2, \tag{24}$$

$$q_{imts} = \tfrac{1}{4}\Big(\phi^0_\gamma[\sigma^{y_0}]_s + \phi^0_\gamma[\sigma^{y_1}]_s + \phi_\gamma[1-\mathrm{HHI}^{y_0}]_s + \phi_\gamma[1-\mathrm{HHI}^{y_1}]_s\Big), \tag{25}$$

$$\mathrm{MS}_{its} = \frac{\sum_m w^{y_1}_{mt}\, q_{imts}}{\sum_m w^{y_1}_{mt}}. \tag{26}$$

A non-supplier scores zero on the shares but keeps the concentration terms. Midstream, the category adds the share of world manufacturing capacity including announced projects for batteries, solar and

wind (International Energy Agency, 2024), over the world total including the source's residual row, and four indices of the EV position of the economy's IEA region. The IEA reports the European Union as one region, so every EU member carries the EU's 2035 share (0.15 in wind, 0.11 in batteries, 0.00 in solar) and members are not ranked apart on it.

Energy Imports. For oil, gas and coal upstream, with production P_{if} and consumption C_{if} of fuel f in exajoules,

$$B_{if} = P_{if} - C_{if}, \qquad \beta_{if} = 100\,\frac{P_{if}}{C_{if}}, \qquad \mathrm{EI}_{if} = \tfrac{1}{2}\Big(\phi_\gamma[\beta]_f + \phi_\gamma[B]_f\Big), \tag{27}$$

the net balance and self-sufficiency, ranked within the fuel, from the Statistical Review for 2025 (Energy Institute, 2026). Where it lists no production for an economy and fuel, production is taken from the EIA's International Energy Statistics (U.S. Energy Information Administration, 2026), counted as observed and paired with consumption of the same year; Estonian coal, for which the Statistical Review counts oil shale, remains missing.

Reserves. Upstream, the category ranks proved oil, gas and coal reserves (end-2020, the last year the Energy Institute publishes them), reserves of nine critical minerals from the USGS Mineral Commodity Summaries 2026 (end-2025, with the erratum that puts Brazil's rare earths at 11 Mt) (U.S. Geological Survey, 2026), and identified recoverable uranium resources below USD 260/kgU from the OECD-NEA/IAEA Red Book (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026). With ρ_{im} the zero-anchored index of mineral m, zero for an unlisted holder,

$$R_{it} = \phi^0_\gamma\Big[\textstyle\sum_{m\in M_t} \tilde{w}^{y_0}_{mt}(M_t)\,\rho_{im}\Big]_t, \tag{28}$$

so a holder of one mineral does not score that mineral's rank for the whole technology. Holders the USGS lists without a figure (not available, withheld or small) count as zero. Downstream, the category scores solar, wind and geothermal resource potential.

Trade. The crosswalk of Section 3.2 assigns each pair a basket of HS six-digit products G_{ts}: nine midstream baskets and, upstream, the raw materials of batteries, electric vehicles (battery-mineral ores and magnet rare earths), wind (rare earths), solar (silicon metal), nuclear (uranium ores and natural uranium compounds), the fossil fuels and the grid, whose basket holds copper and aluminium inputs rather than electricity. The category is

$$c_{\mathrm{T},its} = \mathrm{mean}\Big\{\phi_\gamma[-\mathrm{HHI}_{ts}],\ \phi_\gamma\Big[\frac{\sum_{h\in G_{ts}} X_{ih}}{\sum_{h\in G_{ts}} W_h}\Big]_{ts},\ \phi_\gamma\Big[-\frac{\sum_{h\in G_{ts}}(M_{ih}-X_{ih})}{\mathrm{GDP}_i}\Big]_{ts}\Big\}: \tag{29}$$

the share of world basket exports and net basket imports relative to GDP, from the Atlas of Economic Complexity (The Growth Lab at Harvard University, 2019; Hausmann et al., 2014) and WDI (World Bank, 2026), and the concentration of world basket exports among UN Comtrade reporters in 2024

(United Nations Statistics Division, 2026), which excludes Hong Kong as a re-export hub and is ranked across the 18 basket cells of the headline technologies. That term takes one value per pair, so it moves the pair's level without reordering its economies.

Minerals Trade and Production. Minerals Trade averages the demand-weighted zero-anchored shares of world exports of the technology's minerals (for a non-reporter, partners' reported imports converted from CIF to FOB) with a pair-constant concentration term. Production ranks mine output like reserves,

$$\mathrm{P}_{it} = \phi^{0}_{\gamma}\Big[\textstyle\sum_{m\in M_t} \tilde{w}^{y_0}_{mt}(M_t)\,\pi_{im}\Big]_t, \tag{30}$$

and, for nuclear, uranium mine output from the Red Book. Fossil output enters only through Energy Imports.

Energy Access, Consumption, Prices and Investment. Downstream, Energy Access ranks energy supply per capita in 2025 and its growth since 2020, by fuel; Consumption ranks installed capacity per capita in 2024 and its projected growth to 2035 (BloombergNEF, 2024). Both read a deeper, expanding domestic system as more secure; treating high use as exposure would reverse the sign (Section 6.3). Energy Prices is $\phi_\gamma[-\bar{v}_t]$, with $\bar{v}_t$ the mean annualized volatility of monthly log changes in the technology's IMF commodity prices over 1, 5, 10 and 20 years (International Monetary Fund, 2026b), a world value. Investment ranks clean-technology investment, its three-year momentum, and operating and pipeline manufacturing capacity (Rhodium Group and MIT Center for Energy and Environmental Policy Research, 2026); upstream critical-minerals investment is split between batteries and electric vehicles by their IEA demand shares, 11.5 and 88.5 per cent.

5.3 Results

Coverage. The pillar scores 6,232 cells of the eleven headline technologies for 219 economies (195 sovereign, 24 territories) in 30 of the 33 pairs (Geothermal upstream and midstream and Electric Grid downstream have no category). No pair is constant and no cell fully imputed; the mean imputed weight share is 0.41, 0.23 and 0.27 by stage. All rankings and summaries use the 4,163 rankable cells (Section 4.6): 1,124 of 2,181 upstream, where the world price series places every economy in each pair while the mineral and fossil sources cover far fewer, 1,397 of 2,002 midstream and 1,642 of 2,049 downstream.

Distribution. The median rankable cell scores 0.28 upstream (interquartile range 0.19 to 0.37), 0.46 midstream (0.36 to 0.53) and 0.44 downstream (0.35 to 0.52), with a right-skewed upstream distribution (Figure 8): in the median upstream pair 71 per cent of rankable economies score zero on Reserves and 84 per cent on Production. Technology-stage fixed effects explain 44 per cent of the variance, country effects alone 12 per cent and both together 60 per cent (28 per cent of the within-pair variance), and the pair effects reflect the category bundles rather than the cell-constant

inputs. Rankings are meaningful within a pair; comparing one economy's levels across pairs, as the Strategic Index does, mixes content with construction.

Drivers. The exact category decomposition (equation (19), Figure 9) shows that upstream Trade supplies 31 per cent of the average score, Energy Prices 20, Minerals Trade 16 and Foreign Dependency 13, while Reserves and Production supply 7.2 and 3.1 per cent against mean effective weights of 20 and 19.5 per cent: for the typical economy the registers add nothing, for the few holders they decide the top. Midstream, Trade supplies 73 per cent and Foreign Dependency 26; downstream, Consumption 56 and Energy Access 24. The cell-constant inputs carry a mean effective weight of 0.21 upstream and 0.22 midstream but supply 36 and 26 per cent of the score. Reserves and Production correlate at a within-pair median of 0.84, so upstream the pillar counts mineral endowment twice.

Uranium. Nuclear upstream is scored on Energy Prices, Trade, Reserves and Production, with effective weights of 1/8, 1/4, 1/4 and 3/8 (Figure 10). Of the 195 rankable economies, 58 hold identified resources and 18 of them produce. The 105 economies with neither and without observed uranium trade share one value, 0.172; the other 32 without uranium lie between 0.145 and 0.201. Kazakhstan leads (0.84), ahead of Canada (0.74), Namibia and Australia (0.72); China is tenth (0.56) and the United States eleventh (0.53); 31 of the 57 coalition members hold resources. Read as a need, the common value becomes a uniform 0.83 that measures absence rather than a gap domestic supply could close. Because 86 of the 174 countries with a Strategic Index share it, the allied picks admit an upstream stage only where the country records reserves or production of its resources (Section 9.3), a pick-eligibility rule, not part of the index.

Leaders and the coalition. China leads 11 of the 30 pairs (Table 9): three upstream mineral pairs, five midstream pairs, through its shares of refined supply and manufacturing capacity (International Energy Agency, 2024, 2025a), and three downstream pairs; no other economy leads more than two. Upstream, leadership follows endowments (Saudi Arabia in oil, Qatar in gas, Kazakhstan in nuclear, Chile in the grid and solar); in Oil upstream China ranks 34th, the position of an importer (Figure 11). A coalition member is first in 16 pairs and in the top three of all 30. The 57 members have mean within-pair percentiles of 0.59, 0.72 and 0.62 by stage, against 0.47, 0.41 and 0.50 for other economies (Figure 12); the United States averages 0.95, China 0.92 (0.99 midstream), and Taiwan has the profile of a manufacturer without resources (0.75 midstream, 0.01 upstream). Canada is the one high-income member with a gap in the heatmap: its Downstream Consumption category is imputed at the global average in all eight cells it enters, because the BloombergNEF outlook behind it neither models Canada nor has a North American aggregate, so six of its nine scored Downstream cells are not rankable (the other economies with the whole category imputed are Taiwan, Bermuda and seven South Asian economies). The lead is unsurprising for a coalition of large or resource-rich economies; whether members' strengths complement one another is the subject of Section 11. Online Appendix OA.3 details the leaders, the tiers and the category correlations.

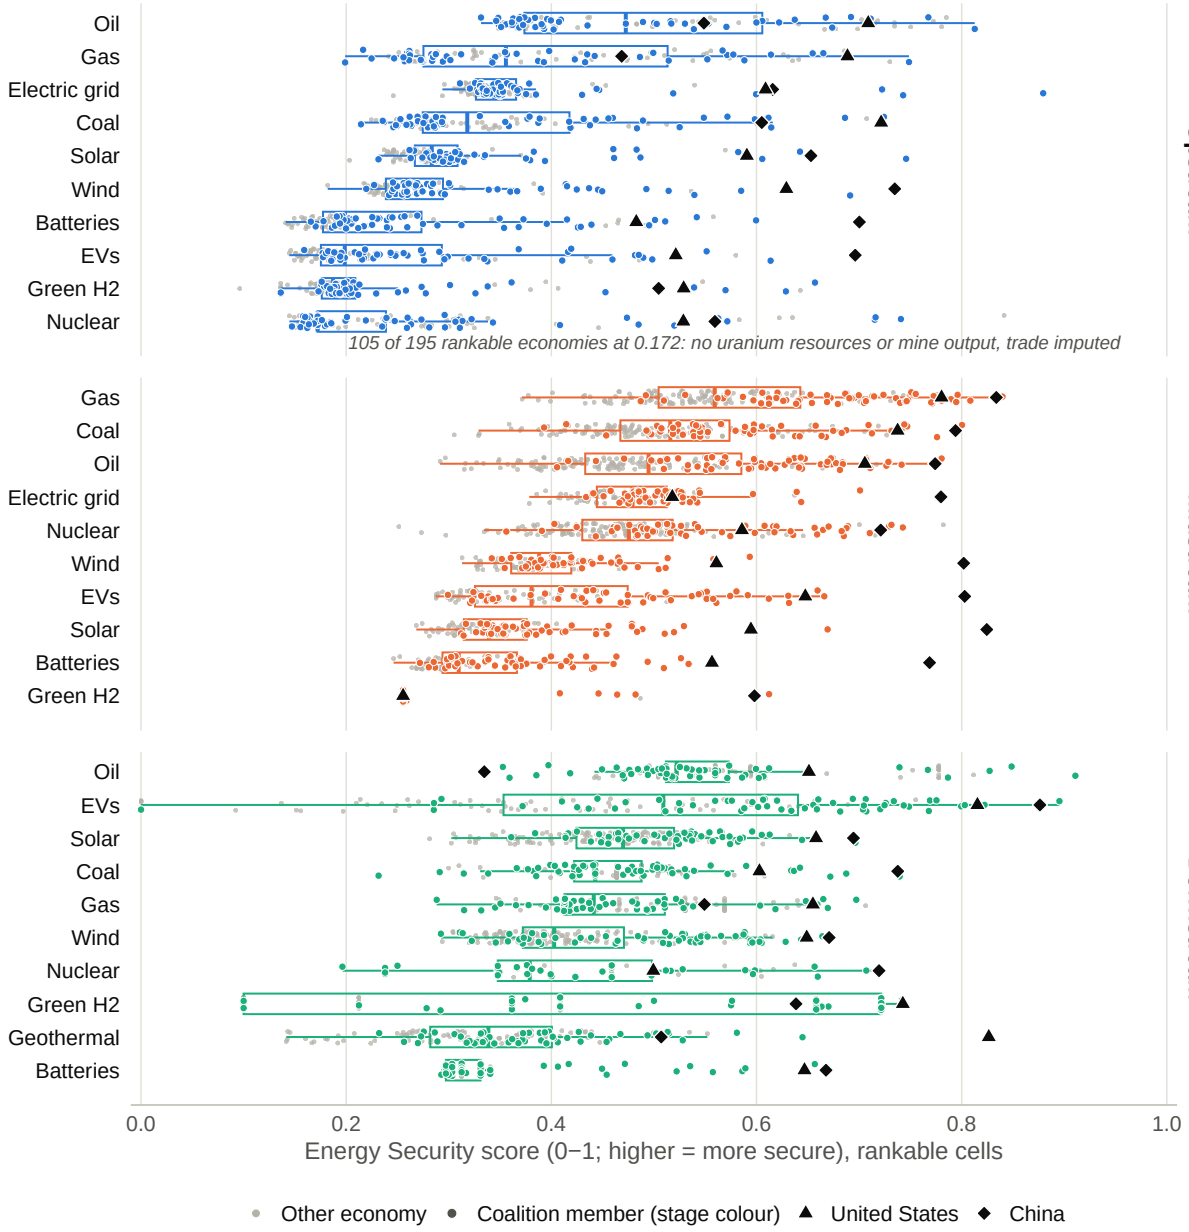

Figure 8: Energy Security by technology and stage, rankable cells (68 to 195 economies per pair; sovereign economy with at most half of the index weight imputed). Boxes span the interquartile range; gray dots are non-members, coloured dots coalition members in the stage colour; the triangle marks the United States and the diamond China. In Nuclear upstream, 105 of the 195 economies, which have neither uranium resources, production nor observed uranium trade, share the value 0.172 (Energy Prices plus an imputed Trade category). In Green Hydrogen midstream 90 per cent of economies share 0.26. Source: `energy_security_index` in `index_outputs.rds`, final run; `scripts/paper/fig_es.R`.

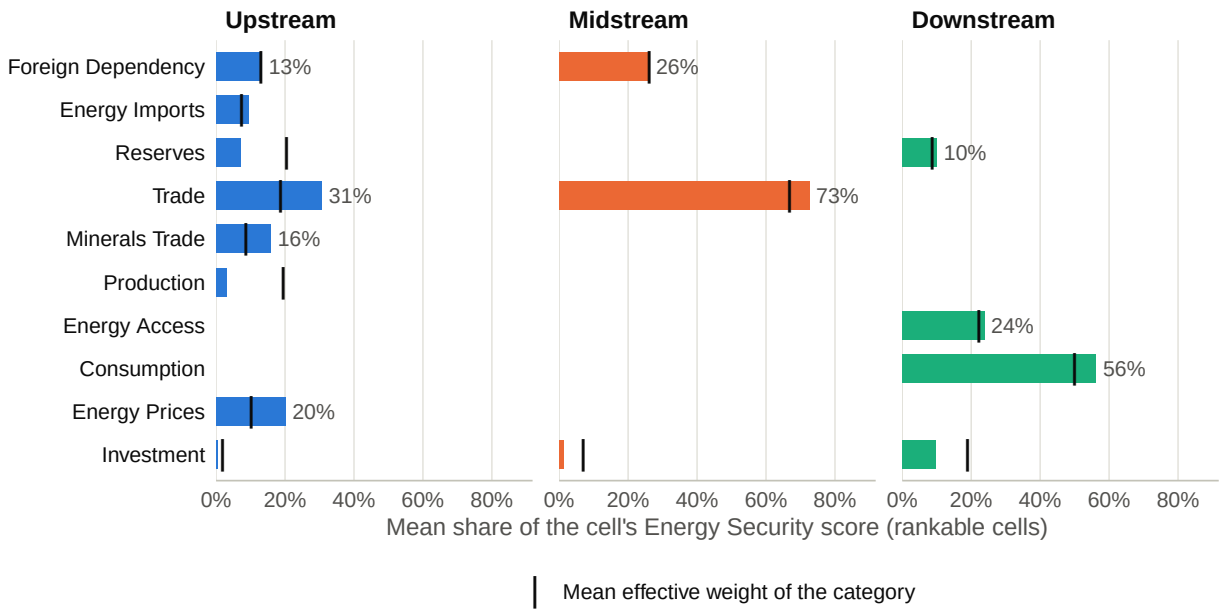

Figure 9: Average composition of Energy Security by stage, rankable cells. Bars: mean share of each category in the score, $\omega_{kits}c_{kits}/\mathrm{ES}_{its}$ (equation (19)); ticks: the category's mean effective weight. A bar much shorter than its tick, as for Reserves and Production upstream, marks a category on which most economies score zero. The upstream Energy Prices and Trade shares include Nuclear upstream (15 and 28 per cent without it). Sample: 1,124 upstream, 1,397 midstream and 1,637 downstream cells. Source: `energy_security_outputs$category_contributions`; `scripts/paper/fig_es.R`.

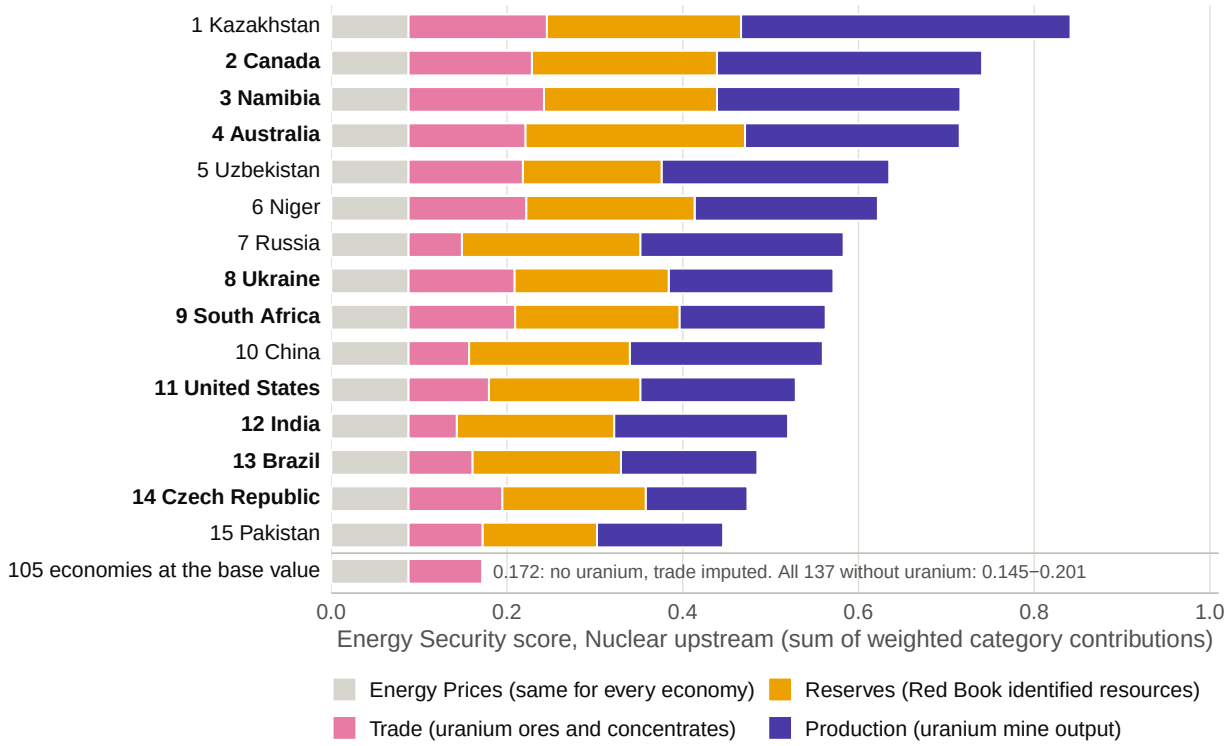

Figure 10: Composition of Energy Security in Nuclear upstream: the 15 highest-ranked of 195 rankable economies (coalition members in bold), split into Energy Prices (uranium price volatility, 0.088 for every economy), Trade (uranium ores, concentrates and natural uranium compounds), Reserves (identified resources below USD 260/kgU, OECD-NEA/IAEA Red Book) and Production (mine output). The bottom row stands for the 105 economies without uranium whose uranium trade is not observed (0.172). Source: `energy_security_index` and its category contributions; `scripts/paper/fig_es.R`.

Notes: ES_{its} for the eleven headline technologies, final run. Only rankable cells enter: a sovereign economy with at most half of the cell's index weight imputed. Economies are identified by ISO3 code and followed by their score; n is the number of rankable economies in the pair. "Best member" is the highest-ranked of the 57 coalition members, with its rank in parentheses; the USA and CHN columns give the ranks of the United States and China. A rank is one plus the number of rankable economies with a strictly higher score, so tied economies share a rank, and a superscript gives the number of economies that share it (the economy listed is the first of them alphabetically). Geothermal upstream, Geothermal midstream and Electric Grid downstream have no Energy Security score. Source: `energy_security_index` in `index_outputs.rds`; `scripts/paper/fig_es.R`.

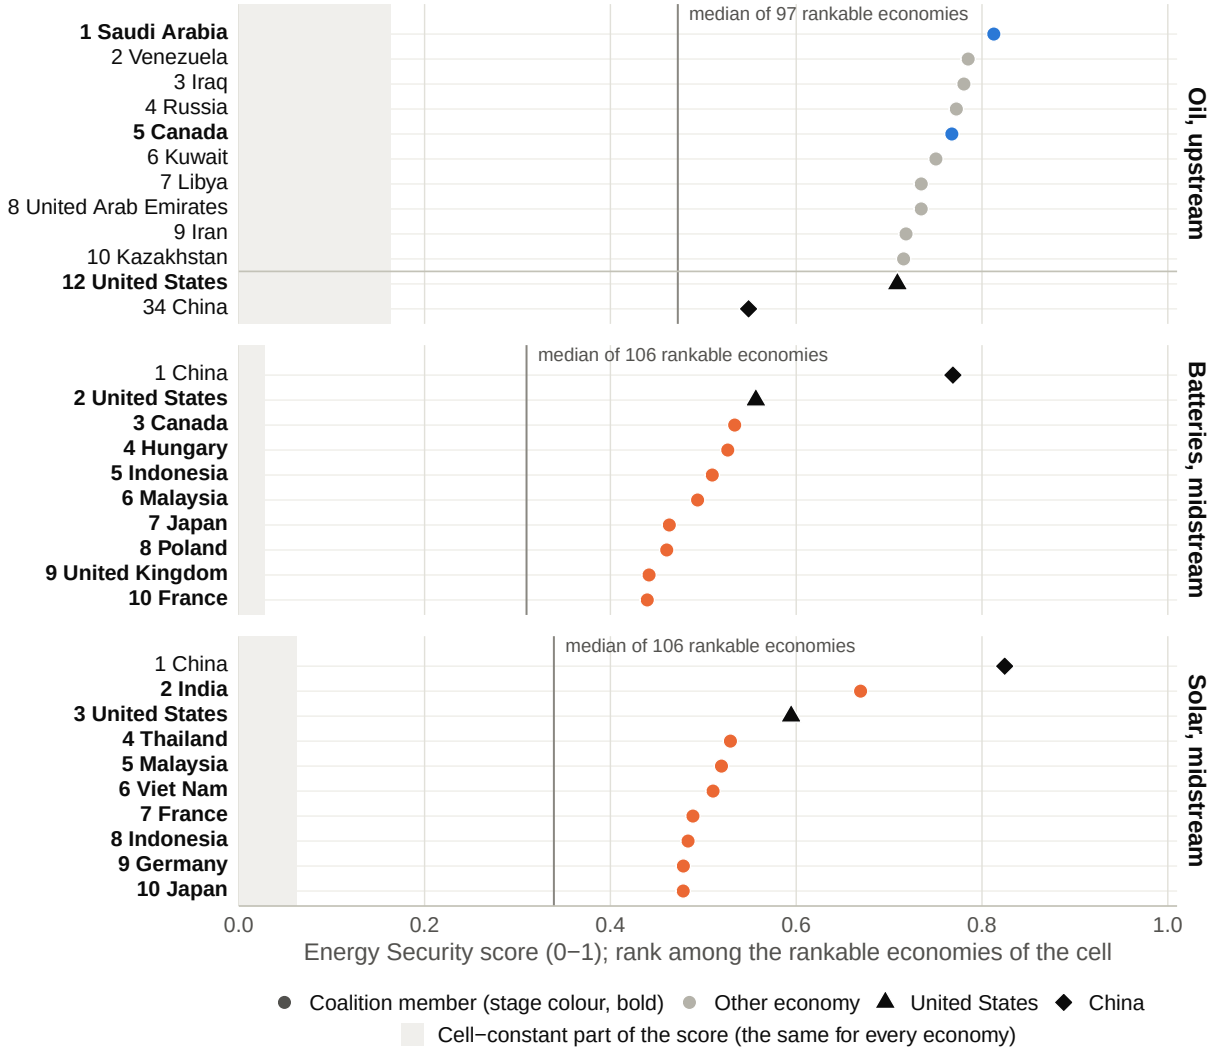

Figure 11: The ten highest-ranked economies in Oil upstream, Batteries midstream and Solar midstream (97, 106 and 106 rankable economies), with the United States (triangle) and China (diamond) appended when outside the top ten. Coalition members are in bold and the stage colour. The vertical line is the pair median; the shaded band is the cell-constant part of the score (0.16, 0.03 and 0.06). Source: `energy_security_index` and its variable contributions; `scripts/paper/fig_es.R`.

Figure 12: Energy Security of the 57 coalition members across the 33 sectors, grouped into the ten core members outside the EU, the 21 core EU members and the 26 partners, each ordered by mean within-pair percentile; China for reference. Colour gives ES_{its} for rankable cells; gray cells are scored but not rankable, crosses unscored, and the three sectors without an Energy Security score are blank. Canada's Downstream cells rest on an imputed Consumption category (its source, the BloombergNEF outlook, does not report Canada), so six of them are not rankable. Source: `energy_security_index` and `coalition_members`; `scripts/paper/fig_es.R`.

Caveats. Several pairs rank few distinct values: in the Strategic Index sample, Green Hydrogen midstream has 34 of 40 countries at one value, Nuclear upstream 86 of 174, Green Hydrogen downstream 45 of 158, Nuclear downstream 19 of 67 and Batteries downstream 38 of 138, and under the need reading each mass point becomes a uniformly high need (Section 9). Unquantified holders count as zero, and the downstream reading treats deeper domestic use of a fossil fuel as security.

6 The Economic Opportunity Index

The Economic Opportunity pillar EO_{its} asks how well placed economy i is to capture value from the expansion of technology t at stage s. Its premise comes from economic complexity: countries diversify into activities close, in capability space, to those they already perform competitively, and relatedness predicts new comparative advantage (Hidalgo et al., 2007; Hausmann and Klinger, 2006; Hausmann et al., 2014; Hidalgo and Hausmann, 2009; Hausmann et al., 2022; Hidalgo, 2021; Hausmann et al., 2007), including in low-carbon products (Mealy and Teytelboym, 2022; Growth Lab at Harvard University, 2024). We apply it at the supply-chain stage, where green industrial policy is now designed (Rodrik, 2014; Juhász et al., 2024), and add market size and growth, cost, technological maturity and committed capital. A higher score means more opportunity; EO_{its} is not the complement of ES_{its} (Section 6.3).

6.1 Construction

Ten categories (Table 10) are combined by the rules of Section 4 into the available-case weighted mean of equation (16). The weights sum to 30: eight categories carry 3, Technology Demand 4 and Technological Readiness 2. $\phi_\gamma[x]_g$ is the S-curve of equation (10) ($\gamma = 0.5$) within comparison set g, by default the pair (t, s). Technological Readiness and the input-cost component of Cost Competitiveness cover all 33 pairs. Technological Readiness, Energy Prices and three of the four Technology Demand components are constant within a pair: by equation (18) they shift a pair's level without reordering its economies. Appendix A lists every variable; Online Appendix OA.4 gives further detail.

6.2 Categories

Trade. Trade measures revealed and latent capability to export the goods of a stage, using the baskets G_{ts} of Section 3.2; the upstream baskets give every upstream pair except Geothermal and Green Hydrogen a Trade category. Besides the Atlas share of world basket exports (The Growth Lab at Harvard University, 2019), shared with ES, it ranks revealed comparative advantage (Balassa, 1965) from UN Comtrade (United Nations Statistics Division, 2026),

$$\mathrm{RCA}_{its} = \frac{E_{its}/T_i}{\sum_{j\in R} E_{jts} / \sum_{j\in R} T_j}, \tag{31}$$

Table 10: Structure of the Economic Opportunity pillar

Category	Weight (share)	Components (stage: technologies)	Sources	Higher score =	Missing rule
Trade	3 (0.10)	Share of world basket exports; Balassa RCA; basket export value; product-space feasibility; world export concentration† (Up, Mid: all but Geo, H_2)	Atlas HS92; UN Comtrade	larger, more specialised exports; closer capabilities; contestable market	avg
Production	3 (0.10)	Level, absolute change and a composite of fossil output (Up: Oil, Gas, Coal), uranium mine output (Up: Nuc), demand-weighted share of world mined mineral supply (Up: Bat, EV, Grid, H_2, Sol, Wind) or power generation (Down: Sol, Wind, Nuc, Coal, Gas, Oil)	EI Statistical Review; EIA; Red Book; IEA Critical Minerals Dataset	larger, faster-growing production	avg
Technology Demand	4 (0.13)	World supply in 2035 and its growth†; regional demand (12 economies) or the EV car market (Down: EV); US addressable market†; manufacturing overcapacity† (Mid: Bat, Sol, Wind, H_2)	IEA WEO 2025; BNEF NEO 2024; IEA GEVO 2026; BCG; BNEF	larger, faster-growing market; less overcapacity	avg
Technological Readiness	2 (0.07)	TRL Index of the items mapped to the technology and stage: bell-shaped level score and capped momentum† (all pairs)	IEA Clean Energy Technology Guide	readiness nearer TRL 6; faster maturation	avg
Energy Prices	3 (0.10)	Commodity price volatility† (Up: all but Geo)	IMF PCPS	lower volatility	avg
Investment	3 (0.10)	Investment; three-year momentum; operating and pipeline manufacturing capacity (Up: Bat, EV; Mid: Bat, EV, Sol, Wind; Down: Bat, EV, Geo, Nuc, Sol, Wind)	Clean Investment Monitor	more investment and capacity	zero
Energy Access	3 (0.10)	Energy supply per capita and its 2020–2025 growth (Down: Coal, Oil, Gas, Sol, Wind, Nuc)	EI Statistical Review	deeper, growing home market	avg
Foreign Dependency	3 (0.10)	Share of world manufacturing capacity incl. pipeline (Mid: Bat, Sol, Wind, H_2); regional EV production position (Mid: EV)	IEA ETP; IEA EV data	larger share of world manufacturing	zero
Cost Competitiveness	3 (0.10)	LCOE Index (Down: Bat, Coal, Gas, Sol, Wind); Input Cost Index of wages and capital costs (all pairs); relative equipment cost (Mid: Bat, Sol, Wind, H_2; Down: H_2)	BNEF; ILOSTAT; IMF; IEA	lower costs	none (LCOE); avg
Consumption	3 (0.10)	Installed capacity per capita and its growth to 2035 (Down: all but EV, Grid)	BNEF NEO 2024	deeper installed base	avg

Notes: Weights from `config/weights.yml`; shares $w_k/30$ apply where every category is observed (equation (16)). Abbreviations as in Table 8. †Constant across economies within a pair. Missing rules from `config/missing_data.yml` (Table 6); "avg" is the global-average rule.

with E_{its} basket and T_i total exports over the reporters R; the value of basket exports E; and latent capability, the mean Atlas distance $\delta_{i\eta}$ to the basket's HS four-digit headings $\mathcal{H}_{ts}$ (Hidalgo et al., 2007),

$$\text{feas}_{its} = 1 - \frac{1}{|\mathcal{H}_{ts}|} \sum_{\eta \in \mathcal{H}_{ts}} \delta_{i\eta}. \tag{32}$$

The fifth component is the world-market concentration term of the ES category, read as contestability. Then

$$c_{\text{T},its} = \text{mean}\Big\{\phi_\gamma[\text{ms}]_{ts},\ \phi_\gamma[\text{RCA}]_{ts},\ \phi_\gamma[E]_{ts},\ \phi_\gamma[\text{feas}]_{ts},\ \phi_\gamma[-\text{HHI}]\Big\}. \tag{33}$$

Hong Kong, a re-export hub, is excluded from the Comtrade measures (RCA, export value, concentration) but keeps its Atlas components, and the concentration term is ranked across the cells of the eleven headline technologies.

Production. Production measures the depth of existing output and its momentum. For oil, gas, coal and uranium upstream and electricity generation downstream, with output $P_{it,y}$ from the Statistical Review (Energy Institute, 2026) (filled from EIA where it lists none, Section 5.2) or the Red Book, and relative and absolute changes g^{rel}, g^{abs} over five years,

$$\text{size}_{its} = \phi_\gamma[P_{\cdot,2025}]_{ts}, \qquad \text{gabs}_{its} = \phi_\gamma[g^{\text{abs}}]_{ts}, \qquad O_{its} = \phi_\gamma\Big[\tfrac{1}{3}\big(\phi_\gamma[P_{\cdot,2025}] + \phi_\gamma[g^{\text{rel}}] + \phi_\gamma[g^{\text{abs}}]\big)\Big]_{ts}. \tag{34}$$

For the six mineral-intensive technologies upstream, mined supply S_{im} of each mineral in the IEA base year y_0 and in 2035 (International Energy Agency, 2026a) enters as a share of base-year world supply W_m, weighted by the technology's demand share $\tilde{w}_{mt}$:

$$\begin{aligned} s^y_{it} &= \sum_m \tilde{w}_{mt}\, \frac{S_{im,y}}{W_{m,y_0}}, \qquad \text{size}_{its} = \phi_\gamma[s^{y_0}]_{ts}, \\ \text{gabs}_{its} &= \phi_\gamma[s^{2035} - s^{y_0}]_{ts}, \qquad O_{its} = \phi_\gamma[2\,\text{size} + \text{gabs} + h_t]_{ts}, \end{aligned} \tag{35}$$

so growth is an absolute change in base-year world-share units and h_t is a concentration term common to the pair. In every cell $c_{\text{P},its} = \frac{1}{3}(\text{size} + \text{gabs} + O)$.

Technology Demand. Four sources each contribute one composite. Two energy outlooks weight growth twice as heavily as size:

$$\text{GD}_t = \phi_\gamma\Big[\tfrac{1}{3}\big(\phi_\gamma[D_{\cdot,2035}] + 2\,\phi_\gamma[D_{\cdot,2035} - D_{\cdot,2024}]\big)\Big], \tag{36}$$

$$\text{RD}_{it} = \phi_\gamma\Big[\tfrac{1}{3}\big(\phi_\gamma[D_{\cdot t,2035}]_t + 2\,\phi_\gamma\big[D_{\cdot t,2035}/D_{\cdot t,2024} - 1\big]_t\big)\Big]_t, \tag{37}$$

where $D_{f,y}$ is world supply of fuel f in the World Energy Outlook's Stated Policies Scenario (International Energy Agency, 2025b), ranked across seven fuels, and $D_{it,y}$ primary energy consumption in the twelve economies BloombergNEF models (BloombergNEF, 2024); downstream electric vehicles use the EV market composite of the Global EV Outlook (International Energy Agency, 2026d)

instead. The third source is BCG's US serviceable addressable market, one value per pair; the fourth is midstream overcapacity, with ρ_t the ratio of manufacturing capacity to forecast demand in BloombergNEF's supply-chain data,

$$\mathrm{OV}_t = 2^{-\rho_t}, \tag{38}$$

so that capacity equal to demand scores 1/2 and each further multiple halves the score (Figure 13c). Then

$$c_{\mathrm{TD},its} = \mathrm{mean}\left\{\mathrm{GD}_t,\ \mathrm{RD}_{it},\ \phi_\gamma[\mathrm{SAM}]_{ts},\ \mathrm{OV}_t\right\}. \tag{39}$$

Technological Readiness. Opportunity is taken to be greatest around the demonstration stage, where learning is fast and first-mover positions are open. The IEA Clean Energy Technology Guide (International Energy Agency, 2026c) grades technology designs by readiness level (TRL) for 2020–2025; its post-TRL-9 adoption stages are read as levels 9 to 11. Ordered rules map each item to a technology and a stage, and a stage without items takes the technology-wide value. For item n with level x_n and change Δ_n,

$$b(x) = \begin{cases} 0, & x \le 2 \text{ or } x \ge 11, \\ \cos\!\left(\frac{\pi}{2}\,\frac{6-x}{4}\right), & 2 < x \le 6, \\ \cos\!\left(\frac{\pi}{2}\,\frac{x-6}{5}\right), & 6 < x < 11, \end{cases} \qquad \psi(\Delta) = \left(\frac{\min\{\max\{\Delta, 0\}, 3\}}{3}\right)^{1/2}, \tag{40}$$

$$\mathrm{TRL}_{ts} = \frac{1}{|N_{ts}|} \sum_{n \in N_{ts}} \left[0.7\, b(x_n) + 0.3\, \psi(\Delta_n)\right], \tag{41}$$

a cardinal index constant within a pair but different across a technology's stages. Of the Guide's 634 items, 253 map to a headline technology; the index runs from 0.31 (Geothermal downstream) to 0.72 (Gas downstream).

Foreign Dependency: manufacturing position. In EO this category measures the production base from which a country can serve world demand. For batteries, solar, wind and green hydrogen (the IEA's electrolyser column) it is the S-curve of the share of world manufacturing capacity including announced projects (International Energy Agency, 2024), over the IEA world total including its residual row; for electric vehicles, four indices of the EV position of the economy's IEA region, whose five regions partition the world. It carries the zero rule. Every EU member takes the EU's regional 2035 share (0.15 in wind, 0.11 in batteries, 0.24 in green hydrogen, 0.00 in solar), so EU members are not ranked apart on it.

Cost Competitiveness. Three components, one per source. The levelised cost of electricity of a benchmark plant (BloombergNEF, 2024), today and in 2050,

$$\mathrm{LCOE}_{it} = \tfrac{1}{2}\Big(\phi_\gamma[-L_{\cdot,y_r}]_t + \phi_\gamma[-L_{\cdot,2050}]_t\Big), \tag{42}$$

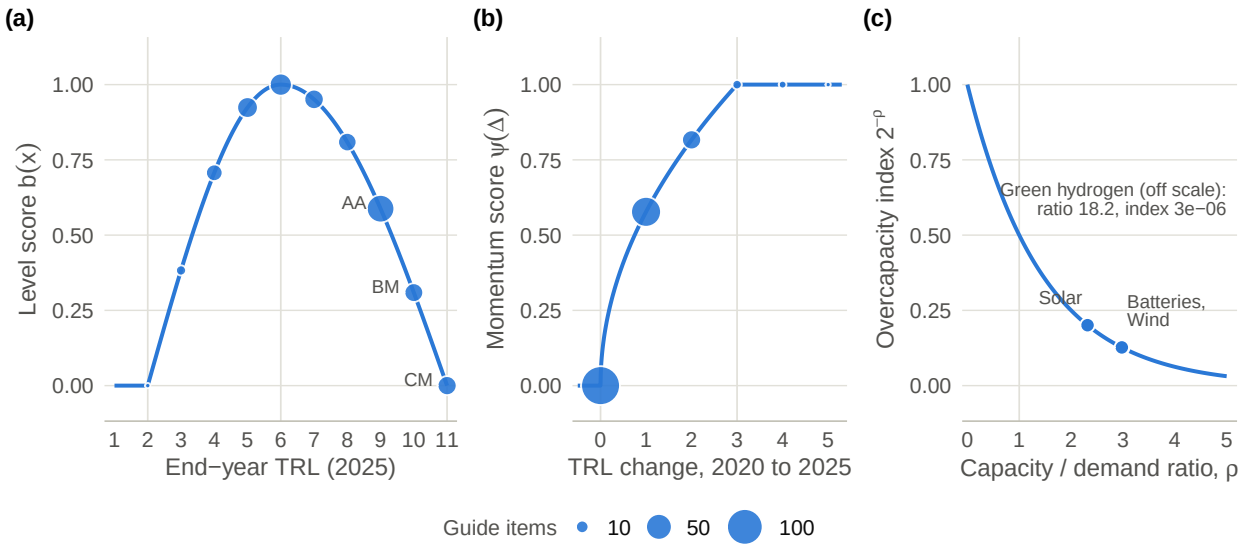

Figure 13: The three cardinal transformations of the Economic Opportunity pillar. (a) The level score $b(x)$ of equation (40) against the 2025 readiness level; circle area is proportional to the number of Guide items mapped to a headline technology at that level (253 items; TRL 9 to 11 are the Guide's adoption stages: awaiting adoption, building momentum, commercial in many markets). (b) The momentum score $\psi(\Delta)$ against the 2020–2025 change, capped at three steps. (c) The overcapacity index $2^{-\rho}$ of equation (38), with the four BloombergNEF technologies at their final-build values (green hydrogen, at $\rho = 18.2$, lies off the scale). Source: the Guide, `technological_readiness_tbl.rds`, `overcapacity_premium_tbl.rds`; `scripts/paper/fig_eo_transforms.R`.

is defined downstream for five technologies, without imputation. The Input Cost Index prices labour, $\ell_{is} = \phi_\gamma[\text{wage}]_s$ (ILOSTAT monthly earnings at market exchange rates in the activity that proxies the stage), and capital, combining the lending rate winsorised and rescaled to $[0, 1]$, R_i, with producer-price inflation,

$$\chi_i = 0.6\, R_i + 0.4\, \phi_\gamma[\text{infl}]_i, \tag{43}$$

weighted by the stage's factor shares (Table 27),

$$\text{ICI}_{its} = \frac{\alpha^L_{ts}}{\alpha^L_{ts} + \alpha^K_{ts}} (1 - \ell_{is}) + \frac{\alpha^K_{ts}}{\alpha^L_{ts} + \alpha^K_{ts}} (1 - \chi_i). \tag{44}$$

The third is the IEA's regional equipment cost relative to China, z_{rt}, and

$$c_{\text{CC},its} = \text{mean}\left\{\text{LCOE}_{it},\ \text{ICI}_{its},\ 1 - \phi_\gamma[z]_t\right\}. \tag{45}$$

Categories common to both pillars. Energy Prices, Investment, Energy Access and Consumption enter EO with the components and index values they have in ES (Section 5.2). Price volatility is read as investment risk for producers, investment and pipeline capacity as revealed investor commitment, and per-capita energy use and installed capacity as the home market.

Table 11: Raw signals shared by the Energy Security and Economic Opportunity pillars

Category (ES / EO weight)	Shared signal	Reading in ES (security)	Reading in EO (opportunity)	Same index values
Energy Access (4 / 3)	EI energy supply per capita, level and growth	availability at the point of use; equally the demand to be secured	depth and growth of the home market	yes
Consumption (5 / 3)	BNEF installed capacity per capita, level and growth	depth of the installed base	home market for equipment and services	yes
Investment (3 / 3)	CIM investment, momentum and capacity	future domestic supply	revealed investor commitment	yes
Energy Prices (2 / 3)	IMF commodity price volatility	price risk for users	investment risk for producers	yes (cell constant)
Trade (4 / 3)	Atlas export market share; world export concentration	a supplier rather than a dependent; few suppliers is a risk	revealed capability; a concentrated market is less contestable	two of three / five
Foreign Dependency (6 / 3)	IEA manufacturing-capacity share; IEA EV regional position	domestic capacity reduces dependence	production base to serve world demand	yes; different missing rules
Production (6 / 3)	mined output of the technology's minerals	domestic supply (demand-weighted, zero-anchored)	demand-weighted share of world supply and its projected change	no

Notes: Nominal category weights of `config/weights.yml` (ES out of 42, EO out of 30). "Same index values": the component enters both pillars as the same theme-level value; imputed values can differ where the missing-data rules or country grids differ.

6.3 Shared signals: exposure and capability

Table 11 lists the raw signals the pillars share, each with the same sign in both. For export share the readings agree; energy use and installed base also measure the demand to be secured; and a concentrated world market may signal an entrenched incumbent, as coded, or unmet demand for an alternative supplier. A shared component induces a positive correlation between the pillars unrelated to any economic link, while in the Strategic Index (equation (55); variable decomposition of equation (20))

$$\frac{\partial \,\mathrm{SI}_{its}}{\partial x_v} = 0.3\,(\omega^{\mathrm{EO}}_{k(v),its}\lambda^{\mathrm{EO}}_{v,its} - \omega^{\mathrm{ES}}_{k(v),its}\lambda^{\mathrm{ES}}_{v,its}), \tag{46}$$

where $\omega^{P}_{k,its}$ is the effective weight of the component's category in pillar P and $\lambda^{P}_{v,its}$ its weight within the category: a shared signal moves the index only as far as it weighs more in one pillar than in the other. The distinctive information lies in the non-shared components, which Section 7 separates.

6.4 Results

Coverage and rankability. The pillar scores 7,131 cells of the eleven headline technologies for 219 economies (195 sovereign, 24 territories) in all 33 pairs, none constant. Twenty-four cells are fully imputed (the Isle of Man 14, Puerto Rico 8, Liechtenstein 2); the mean imputed weight share is

0.43 (0.41, 0.44 and 0.43 by stage). The rankability rule admits 4,301 cells for 178 economies, from 40 in Green Hydrogen midstream to 175 in Nuclear upstream. The excluded cells would mostly have ranked low: they hold only three of the 330 top-ten places computed over all scored economies, and no first place.

Distribution and variance. The median rankable cell scores 0.500 upstream, 0.501 midstream and 0.488 downstream (interquartile ranges 0.434–0.542, 0.427–0.561 and 0.427–0.551; Figure 14). Differences between technologies dominate: pair medians range from 0.367 to 0.585 upstream and from 0.351 to 0.579 midstream, against a mean within-pair interquartile range of 0.037 and 0.082. The clean-technology midstream pairs sit lowest because they carry Foreign Dependency and Investment under the zero rule. Technology-stage fixed effects explain 57.9 per cent of the variance, country effects alone 17.7 per cent and both 77.2 per cent (45.8 per cent of the within-pair variance; ES: 44.4 and 27.8 per cent). Cross-pair comparisons of EO levels, as in the Strategic Index, compare mostly pair effects.

Drivers. In the level (Figure 15), Cost Competitiveness has the largest share at every stage (21.9, 29.2 and 27.5 per cent), followed by Technology Demand. In the within-pair variance, Technological Readiness and Energy Prices contribute nothing and Technology Demand 2 to 6 per cent; the categories that order economies are Cost Competitiveness (39.2, 37.6 and 21.7 per cent by stage), Trade and Production upstream, Trade and Foreign Dependency midstream, and Consumption and Investment downstream. Six technology-level constants carry 38.9 per cent of the average rankable cell's effective weight (46.3, 40.4 and 27.9 per cent by stage), imputed country inputs 17.5 per cent and observed country-specific information 43.6 per cent (Table 12): the pillar's cross-country content is thinnest upstream.

Leaders. China leads 22 of the 33 pairs, the United States five, Chad three, and Canada, Indonesia and Saudi Arabia one each (Table 13); emerging economies, mostly China, hold 26 first places and 46.4 per cent of the top-ten places. Chad's three pairs (Geothermal upstream and midstream, Electric Grid downstream) are those in which only Cost Competitiveness varies, and its leads rest on a recorded lending rate at the floor of the rescaled rate: artefacts, not evidence of opportunity. The median leader's margin is 0.043; China's in Green Hydrogen, Wind, Solar and Batteries midstream are 0.14 to 0.20. In Batteries midstream (Figure 17) China's lead over the United States comes from its manufacturing share and costs; in Solar midstream five Southeast Asian partners take five of the top ten places.

The coalition. Over their rankable cells the 31 core members have a mean within-pair percentile of 0.66, the 26 partners 0.49, other economies 0.44 and China 0.96 (Figure 16). The core is strongest midstream (0.73). The best-placed member is first in 8 pairs and in the top three of 30; in 14 pairs it is a partner, and Indonesia ranks second behind China in five upstream mineral pairs. Both ends of the member ranking are partly construction: four members (Türkiye, Brazil, Argentina, Ghana)

Table 12: Effective weight of the Economic Opportunity pillar by type of input

	Mean effective weight (per cent)			Constants' share
	Technology-level constants	Imputed, country-varying	Observed, country-varying	of the level (per cent)
Upstream	46.3	19.7	33.9	44.0
Midstream	40.4	14.6	45.0	40.2
Downstream	27.9	17.4	54.7	30.4
All rankable cells	38.9	17.5	43.6	38.7
All scored cells	37.7	30.1	32.3	39.5

Notes: The effective weight of variable v in cell (i, t, s) is the renormalised category weight times the variable's weight within its category, $\omega_{kits}\lambda_{vkits}$ (equation (20)); it sums to one in every cell. Technology-level constants are the variables whose value has zero range across all scored economies of the pair: the TRL Index (one value per technology and stage), the WEO global-demand composite, the BCG addressable market, the overcapacity index, the world-market concentration term of Trade and commodity-price volatility. Imputed components are those filled by a missing-data rule (global average or zero) for the economy in question. The first three columns sum to 100 within a row, up to rounding. The last column is the mean share of EO_{its} contributed by the constants. Rows by stage and "All rankable cells": means over the 1,681 upstream, 1,307 midstream and 1,313 downstream rankable cells of the eleven headline technologies (a sovereign economy with at most half of the cell's weight imputed); "All scored cells": means over all 7,131 scored cells. Source: `economic_opportunity_variable_contributions` in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_eo.R`.

record nominal lending rates at the winsorisation ceiling, which depresses every pair, and the BNEF regional composite ranks some modelled economies below unmodelled ones (Online Appendix OA.4).

Notes: EO_{its} for the eleven headline technologies. Only rankable cells enter: a sovereign economy with at most half of the cell's index weight imputed (`config/rankability.yml`). Economies are identified by ISO3 code and followed by their score; n is the number of rankable economies in the pair (40 to 175). "Best member" is the highest-ranked of the 57 coalition members (31 core, 26 partners), with its rank in parentheses; the USA and CHN columns give the ranks of the United States and China. A rank is one plus the number of rankable economies with a strictly higher score. All 33 pairs are scored and none is constant across economies. In geothermal upstream and midstream and electric-grid downstream, Cost Competitiveness is the only category that varies across economies. Codes: AUS Australia, AUT Austria, CAN Canada, CHL Chile, CMR Cameroon, COG Congo, DEU Germany, ESP Spain, FRA France, HUN Hungary, IDN Indonesia, IND India, IRN Iran, ITA Italy, JPN Japan, KAZ Kazakhstan, POL Poland, PRT Portugal, QAT Qatar, RUS Russia, SAU Saudi Arabia, TCD Chad, TGO Togo, THA Thailand, VNM Viet Nam, ZMB Zambia, USA United States, CHN China. Source: `economic_opportunity_index` in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_eo.R`.

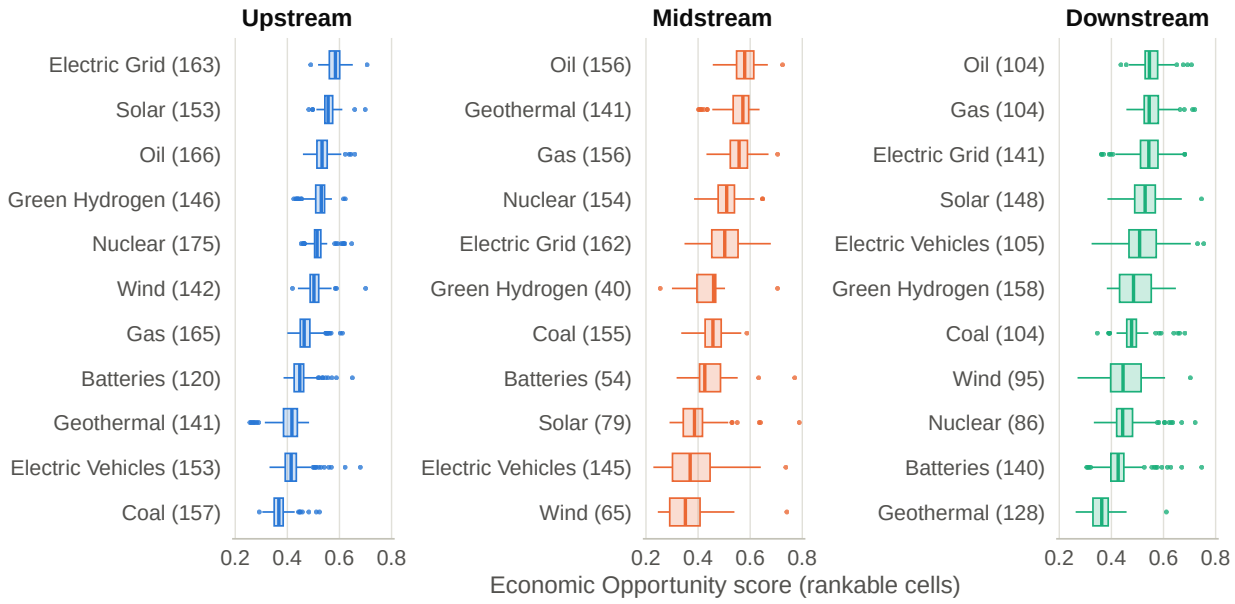

Figure 14: Economic Opportunity by technology and stage over the rankable economies of each pair (number in parentheses, 40 to 175; sovereign economy with at most half of the index weight imputed). Boxes show the median and interquartile range, whiskers 1.5 interquartile ranges. Sample: 4,301 rankable of 7,131 scored cells; all 33 pairs have status *ok*. Source: `economic_opportunity_index` in `index_outputs.rds`; `scripts/paper/fig_eo.R`.

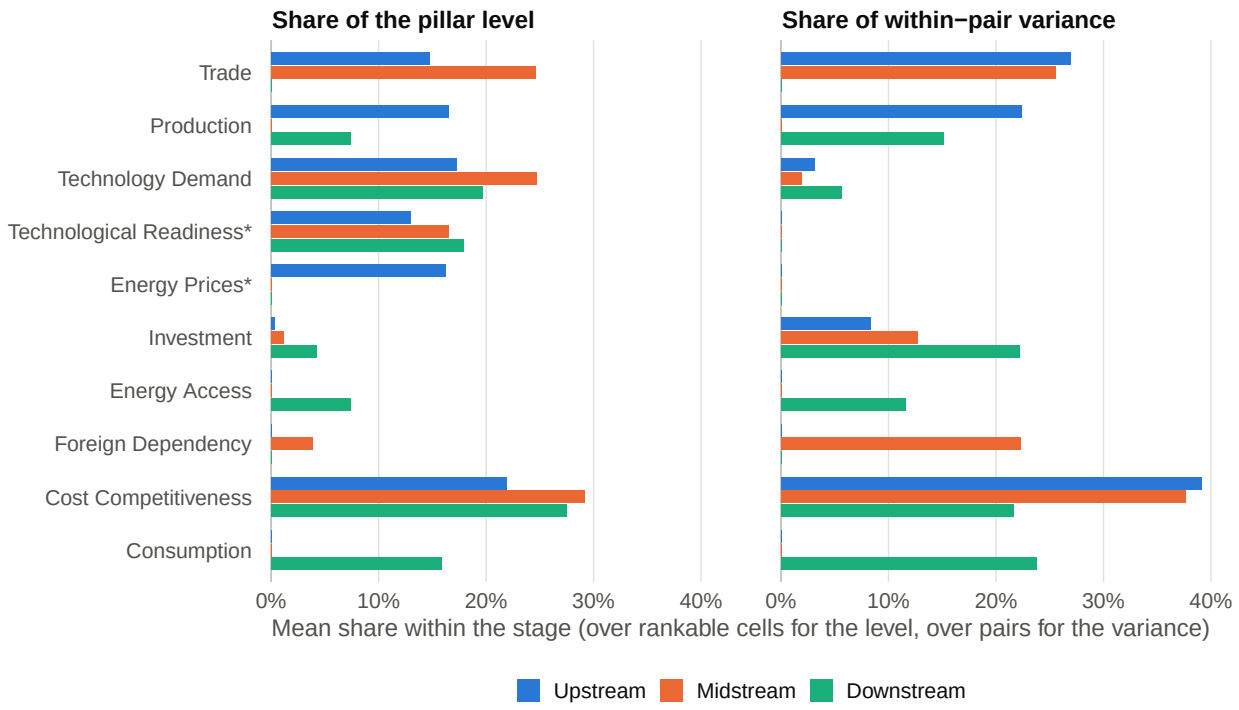

Figure 15: Composition of Economic Opportunity by stage. Left: mean share of each category in the level, $\omega_{kits}c_{kits}/\mathrm{EO}_{its}$ (equation (19)). Right: mean share in the within-pair variance, $\mathrm{cov}(\omega_{kits}c_{kits}, \mathrm{EO}_{its})/\mathrm{var}(\mathrm{EO}_{its})$. Starred categories (Technological Readiness, Energy Prices) are constant within every pair; Technology Demand is constant except for its BNEF regional and EV-market composites. Sample: 4,301 rankable cells. Source: category contributions in `index_outputs.rds`; `scripts/paper/fig_eo.R`.

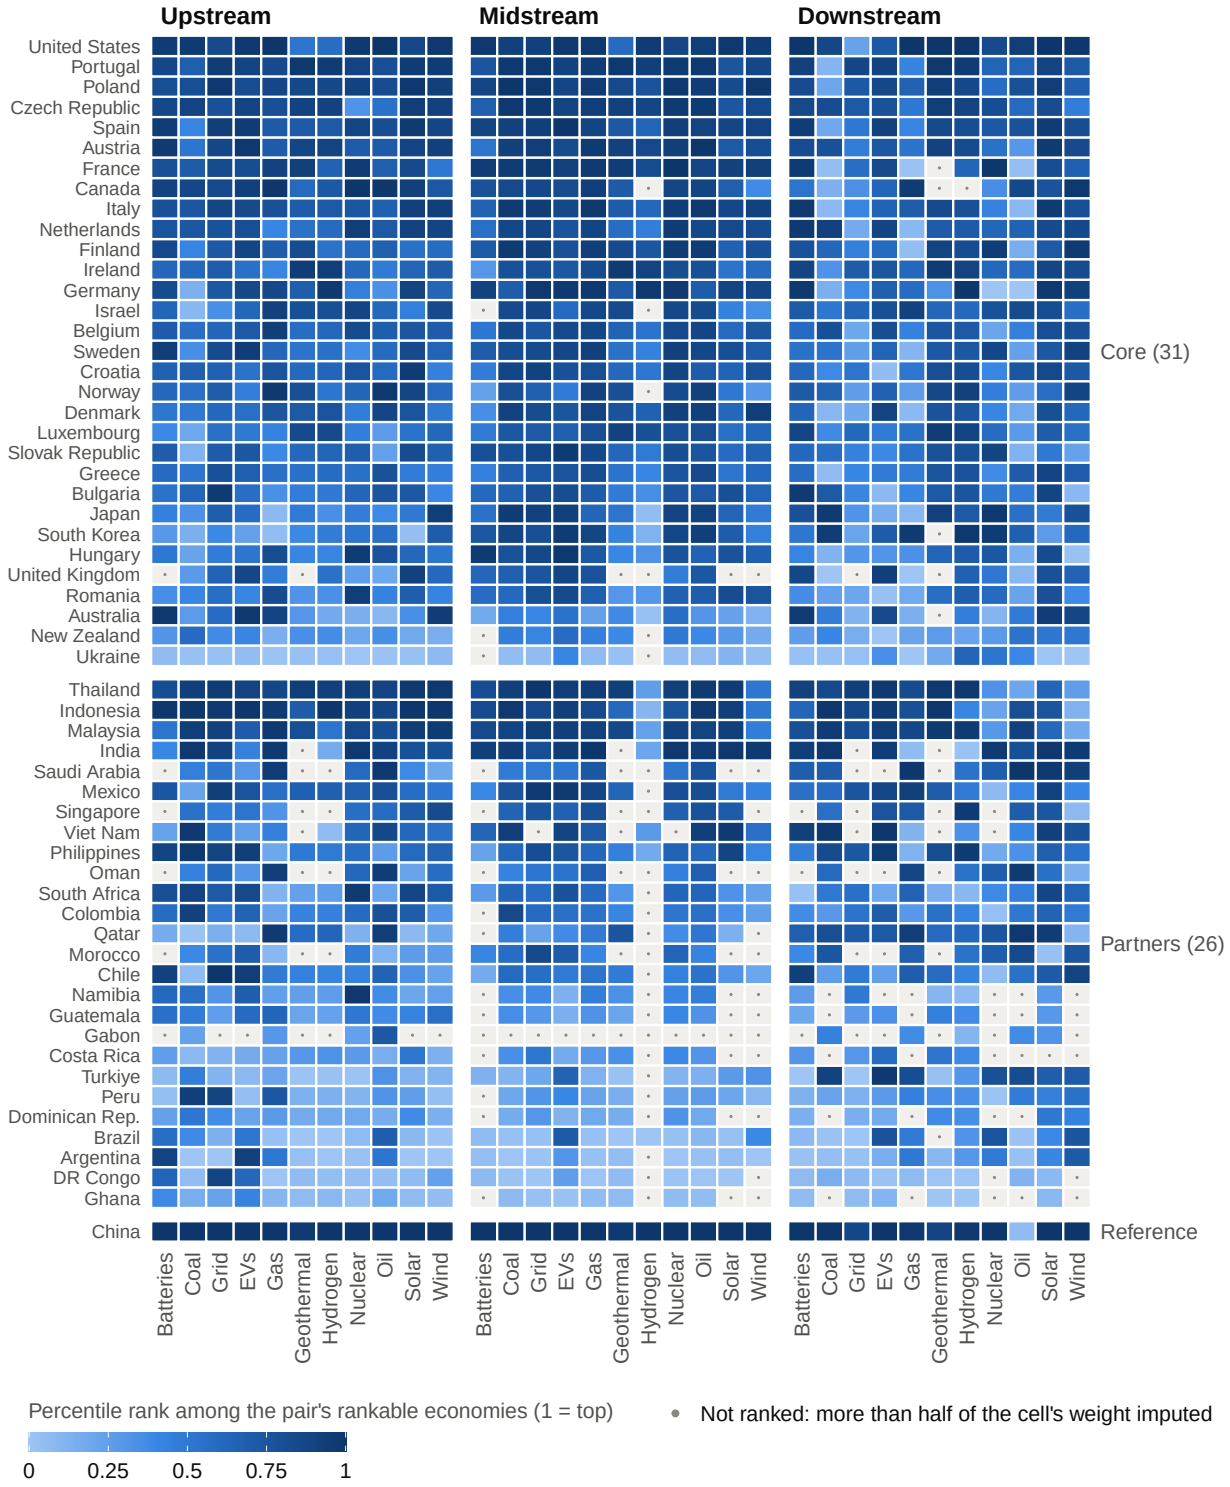

Figure 16: Within-pair percentile rank of EO_{its} (equation (9)) of the 31 core members, the 26 partners (Section 8) and China, by pair. Ranks rather than levels are shown because pair effects account for 58 per cent of the variance of the level. Gray cells with a dot are scored but not rankable (more than half of the weight imputed). Source: `economic_opportunity_index`, `coalition_members`; `scripts/paper/fig_eo.R`.

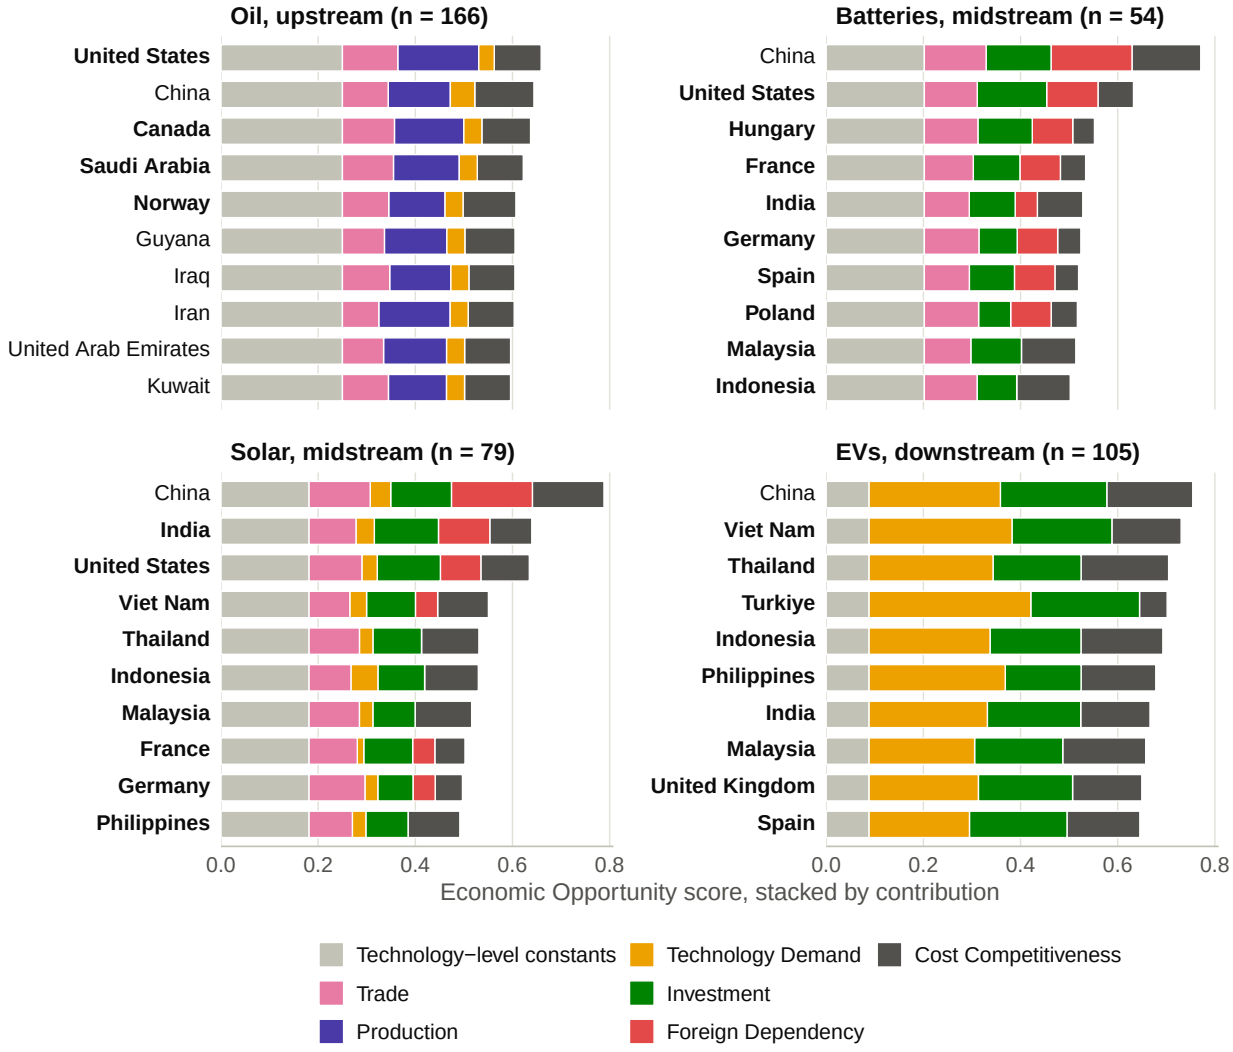

Figure 17: The ten highest-scoring rankable economies in Oil upstream ($n = 166$), Batteries midstream (54), Solar midstream (79) and EV downstream (105), stacked by the variable decomposition of equation (20); colour identifies the category. The gray segment sums the technology-level constants (0.250, 0.202, 0.181 and 0.088), the same for every economy in a pair. Coalition members in bold. Source: `economic_opportunity_index` and its variable contributions; `scripts/paper/fig_eo.R`.

7 The opportunity-security space

Each country-technology-stage cell is a point $(\mathrm{ES}_{its}, \mathrm{EO}_{its})$ of the unit square. The Strategic Index of Section 9 reads the two pillars together, and its pillar terms in equation (55) carry equal weights of opposite sign, so they reduce to the gap between opportunity and security:

$$0.3\,\mathrm{EO}_{its} + 0.3\,(1 - \mathrm{ES}_{its}) = 0.3 + 0.3\,\Delta_{its}, \qquad \Delta_{its} \equiv \mathrm{EO}_{its} - \mathrm{ES}_{its}. \tag{47}$$

The index favours cells in which opportunity exceeds security, and treats alike a cell that is secure and well placed and one that is neither. Because it ranks a country's own sectors, what matters is how Δ_{its} varies across them:

$$\mathrm{Var}_i(\Delta) = \mathrm{Var}_i(\mathrm{EO}) + \mathrm{Var}_i(\mathrm{ES}) - 2\,\mathrm{Cov}_i(\mathrm{EO}, \mathrm{ES}). \tag{48}$$

If the pillars rise together across a country's sectors, the gap is compressed and the policy term and sector priors move the ranking more than their nominal weights suggest (Paruolo et al., 2013; Becker et al., 2017).

Part of the association is built in. Four categories enter both pillars with identical values, and Trade and Foreign Dependency share components (Table 11). By the variable decomposition of equation (20), each pillar splits into the contribution of the shared components and of the rest, $P_{its} = A^P_{its} + B^P_{its}$, and for any set of cells

$$\mathrm{Cov}(\mathrm{ES}, \mathrm{EO}) = \mathrm{Cov}(A^{\mathrm{ES}}, A^{\mathrm{EO}}) + \mathrm{Cov}(A^{\mathrm{ES}}, B^{\mathrm{EO}}) + \mathrm{Cov}(B^{\mathrm{ES}}, A^{\mathrm{EO}}) + \mathrm{Cov}(B^{\mathrm{ES}}, B^{\mathrm{EO}}). \tag{49}$$

With fixed weights the first term is a positively weighted sum of the covariances of the shared components: it records construction, not an economic link. In the gap those components enter with coefficients $\omega^{\mathrm{EO}}\lambda^{\mathrm{EO}} - \omega^{\mathrm{ES}}\lambda^{\mathrm{ES}}$ and partly cancel (equation (46)), so the information on where the gap is large lies mainly in B^{ES} and B^{EO}.

We report within-pair rank correlations from the full pillars and from B^{ES} and B^{EO} alone, and classify cells by each pillar's position relative to its within-pair median. The four regions correspond to the four strategic postures of Carey et al. (2025), which read the same two-dimensional space, in the labelling of the dashboard built on these indices: opportunity without security (leapfrog: build capability), leaders (export promotion), laggards (friendshore: secure supply by investing in and sourcing from aligned partners, the case of Sections 10 and 11) and security without opportunity (alternative value creation). The correspondence is a reading aid, with the median of each pair as the cut. As New Energy Industrial Strategy Center (2026) stresses, security risk and economic opportunity are not synonyms, and the same exposure can warrant different postures; the results below measure how far the two pillars carry distinct information.

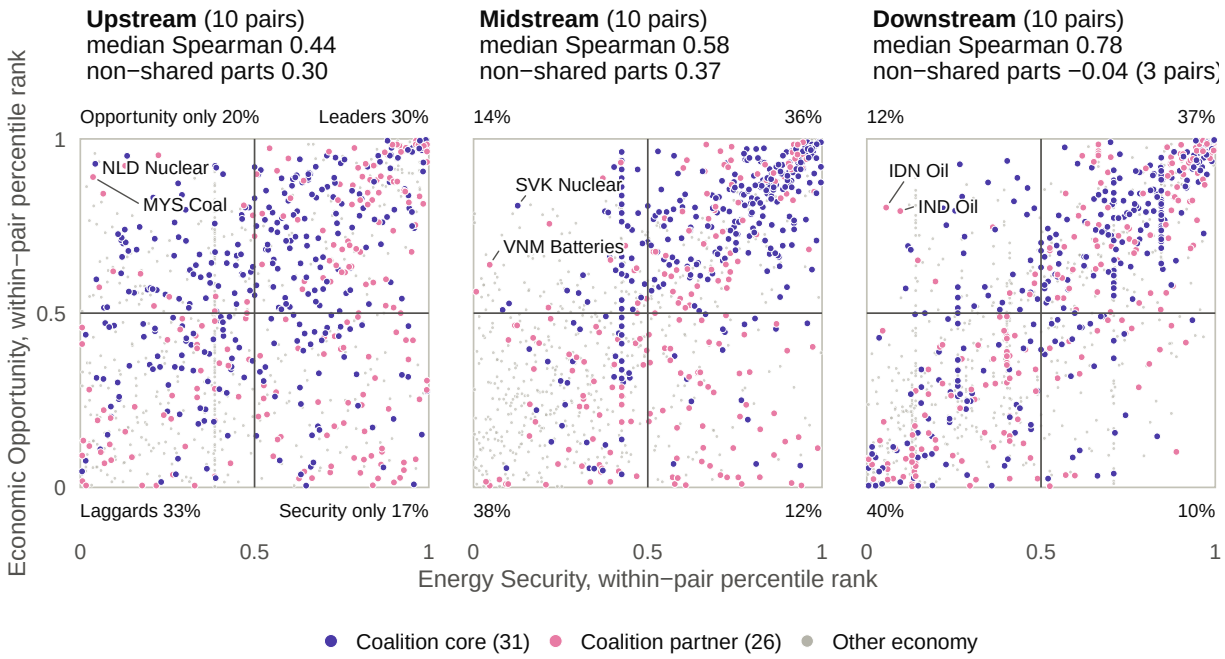

Figure 18: The opportunity-security space. Each point is a cell rankable on both pillars, at its within-pair percentile rank on ES_{its} (horizontal) and EO_{its} (vertical); panels are stages. Violet: the 31 core members; pink: the 26 partners; gray: other economies. Lines at 0.5 mark the within-pair medians and divide the regions (a cell at the median counts as low); corner percentages are the stage's shares. Panel headers give the median within-pair Spearman correlation from the full pillars and from the non-shared parts B^{ES}, B^{EO} of equation (49). The dense column left of the upstream security median is Nuclear upstream, where 87 of 175 economies without uranium share $\mathrm{ES}_{its} = 0.172$. Sample: 3,157 cells, 175 economies, 30 pairs. Source: `index_outputs.rds`; `scripts/paper/fig_joint.R`.

7.1 Results

Sample and co-movement. Both pillars score 6,232 cells; 3,157 cells for 175 economies in 30 pairs are rankable on both (607 territory cells and 2,468 sovereign cells over the imputation threshold are set aside), among them 1,500 cells of the 57 coalition members. The median within-pair Spearman correlation of ES_{its} and EO_{its} is 0.59 (interquartile range 0.45 to 0.77), from −0.21 in Green Hydrogen midstream to 0.94 in Electric Vehicles midstream (Table 14). It rises along the chain: 0.44 upstream, 0.58 midstream and 0.78 downstream (Figure 18), a gradient that also holds within most technologies.

How much is mechanical. Shared components carry 61 per cent of the effective weight of ES_{its} (25, 62 and 91 per cent by stage) but 28 per cent of that of EO_{its}; in seven downstream pairs every security component also enters opportunity. On the 23 pairs where both pillars keep components of their own, the median correlation falls from 0.55 to 0.30 when only non-shared components are used. The shared term accounts for 61 per cent of the pooled within-pair covariance (7, 42 and 87 per cent by stage). What remains runs mainly through trade: the largest cross-pillar category

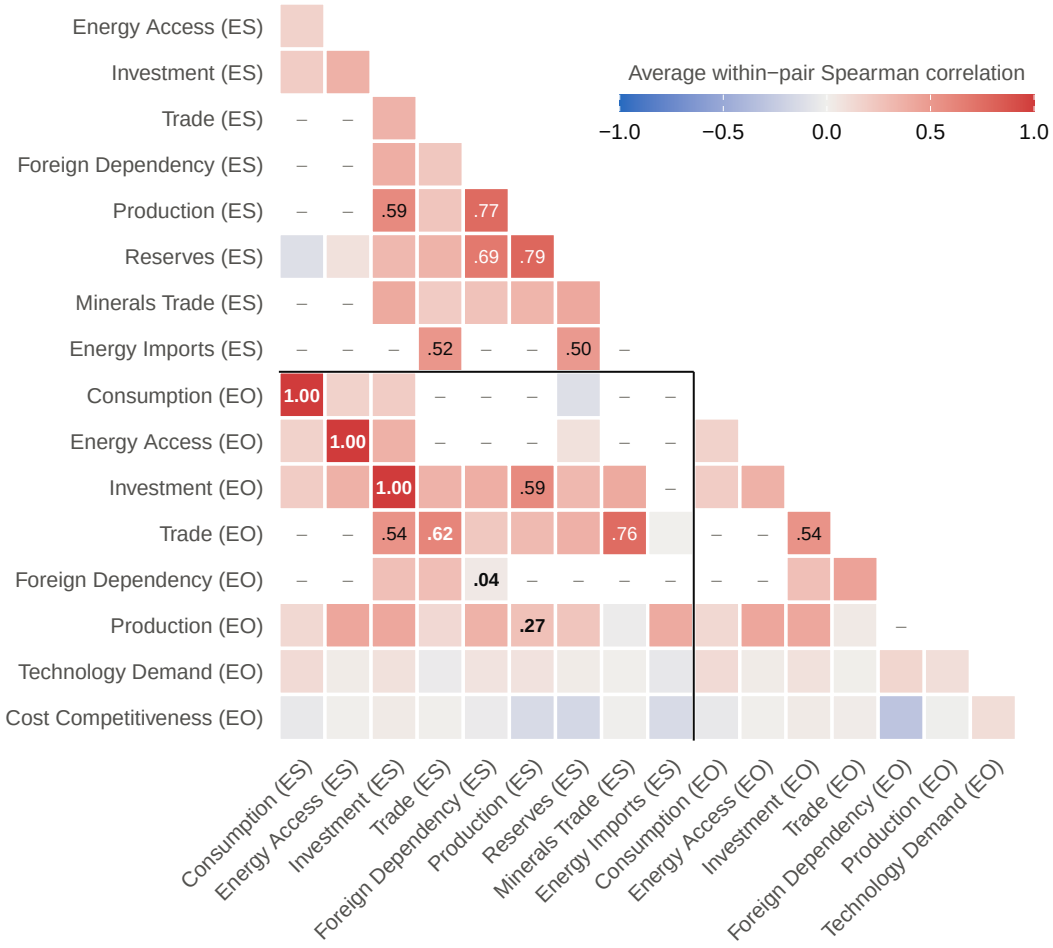

Figure 19: Average within-pair Spearman correlation between the categories of the two pillars (pairs with at least 20 rankable economies in which both categories vary). The black lines separate the cross-pillar block (bottom left) from the within-pillar blocks; bold numbers mark categories entering both pillars under the same name. Energy Prices and Technological Readiness, constant within every pair, are omitted. Sample: as Figure 18. Source: category scores in `index_outputs.rds`; `scripts/paper/fig_joint.R`.

correlation is between security's Minerals Trade and opportunity's Trade (0.76), while Technology Demand and Cost Competitiveness are nearly orthogonal to every security category (Figure 19). Net of shared inputs, security and opportunity are close to unrelated across economies except where exports reveal both.

Regions. Pooling all pairs, 15.1 per cent of cells have opportunity without security, 34.6 per cent are leaders, 13.2 per cent have security without opportunity and 37.1 per cent are laggards (12.6, 37.7, 15.3 and 34.4 per cent if ties count as high). The shares largely restate the rank correlation: a Gaussian copula with each pair's correlation implies an off-diagonal share of 14.6 per cent, against 14.2 observed. Opportunity without security is most common upstream (19.5 per cent), where the pillars are least related. The largest pair shares, Green Hydrogen midstream (45 per cent) and Nuclear upstream (28), are tie artefacts (Figure 20); without them the pooled share is 14.0 per cent.

Table 14: Energy Security and Economic Opportunity within technology-stage pairs, by stage

	Upstream	Midstream	Downstream	All
Technology-stage pairs	10	10	10	30
Country cells	999	1,048	1,110	3,157
Spearman correlation of ES_{its} *and* EO_{its} *within pairs*				
Median across pairs	0.44	0.58	0.78	0.59
Lowest pair	0.03	−0.21	0.40	−0.21
Highest pair	0.63	0.94	0.92	0.94
Pooled within-pair ranks	0.39	0.60	0.71	0.57
Components shared by the two pillars				
Effective weight in ES	0.25	0.62	0.91	0.61
Effective weight in EO	0.26	0.20	0.37	0.28
Pairs with both non-shared pillars defined	10	10	3	23
Median correlation, non-shared pillars	0.30	0.37	−0.04	0.30
Median correlation, full pillars, same pairs	0.44	0.58	0.58	0.55
Share of level covariance, shared term	0.07	0.42	0.87	0.61
Share of level covariance, non-shared term	0.58	0.20	0.00	0.16
Share of cells by region of the space (percent)				
Opportunity without security	19.5	13.8	12.4	15.1
Leaders (both high)	30.2	36.0	37.2	34.6
Security without opportunity	17.2	12.5	10.2	13.2
Laggards (both low)	33.0	37.7	40.2	37.1

Notes: Eleven headline technologies; cells rankable on both pillars only (a sovereign economy with at most half of the pillar's weight imputed), which leaves 3,157 of the 6,232 cells that both pillars score, for 175 economies. A technology-stage pair enters when both pillars score it and neither pillar's diagnostics flag it as constant or unscored, which leaves 30 of the 33 pairs: Energy Security does not score downstream grid or upstream and midstream geothermal. Correlations are Spearman correlations across economies within a pair; the pooled row is the Pearson correlation of within-pair percentile ranks over all cells of the stage. A component is shared when the other pillar contains a component of the same category with identical observed values; its effective weight is its category weight times its within-category weight, averaged over cells. Non-shared pillars are the weighted means of the remaining components with the weights renormalised; they are undefined where every component of ES is shared, as in 7 downstream pairs, and the last two correlation rows use only the pairs in which both are defined. The covariance shares decompose the within-pair covariance of the pillar levels as in equation (49), pooled over pairs with weights $n-1$: the shared term is $\mathrm{Cov}(A^{\mathrm{ES}}, A^{\mathrm{EO}})$, the non-shared term $\mathrm{Cov}(B^{\mathrm{ES}}, B^{\mathrm{EO}})$, and the two cross terms make up the remainder. Regions are defined by the within-pair medians of the two pillars, a cell at the median counting as low. Source: `index_outputs.rds`; `scripts/paper/fig_joint.R`.

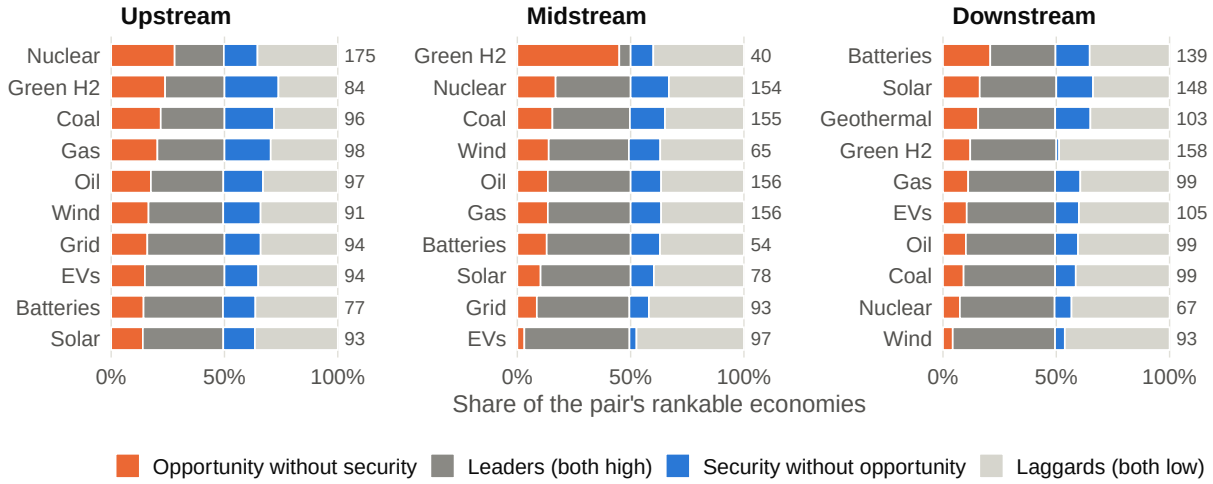

Figure 20: Shares of each pair's rankable economies in the four regions of Figure 18, by stage, ordered by the share with opportunity but not security (orange); blue marks security without opportunity, dark gray leaders, light gray laggards. The two longest orange segments are ties at the security median: in Green Hydrogen midstream 34 of 40 economies share the lowest ES_{its}, and in Nuclear upstream 87 of 175 share the median value. Source: as Figure 18.

The coalition. Of the members' cells, 49.3 per cent are leaders and 12.8 per cent have opportunity without security (core 55.1 and 16.4 per cent, partners 40.4 and 7.4; Figure 21), partly because scale raises both pillars; the United States is a leader in 29 of 30 pairs. Austria, Portugal and Luxembourg have the most leapfrog-type pairs (11 of 30 each); Brazil (19 of 29), Peru and Türkiye have the most security without opportunity.

Within countries and the Strategic Index. Across the sectors of each of the 167 countries with at least five Strategic Index cells, the correlation of EO_{its} and ES_{its} averages 0.46 (from -0.56 to 0.84), and the covariance term removes on average 36 per cent of $\mathrm{Var}_i(\mathrm{EO}) + \mathrm{Var}_i(\mathrm{ES})$ (42 per cent for members), leaving a standard deviation of Δ_{its} of 0.13. The index does favour the leapfrog region (mean 0.563 there, against 0.511 to 0.545 elsewhere), and 8 of the 57 allied picks lie in it (14.0 per cent, against 6.7 per cent of eligible sectors). Four of the nine Nuclear midstream picks come from small partners with four or five eligible sectors; their security ranks lie at or above a compressed median, so the picks reflect the technology weight of equation (55) (0.999 for nuclear against 0.42 for gas), not a security floor. Across a country's sectors the index correlates 0.63 with the level gap but only 0.19 with the gap in within-pair ranks: it reflects which pairs score high opportunity and low security for everyone at least as much as where the country stands. Online Appendix OA.5 gives further detail and caveats.

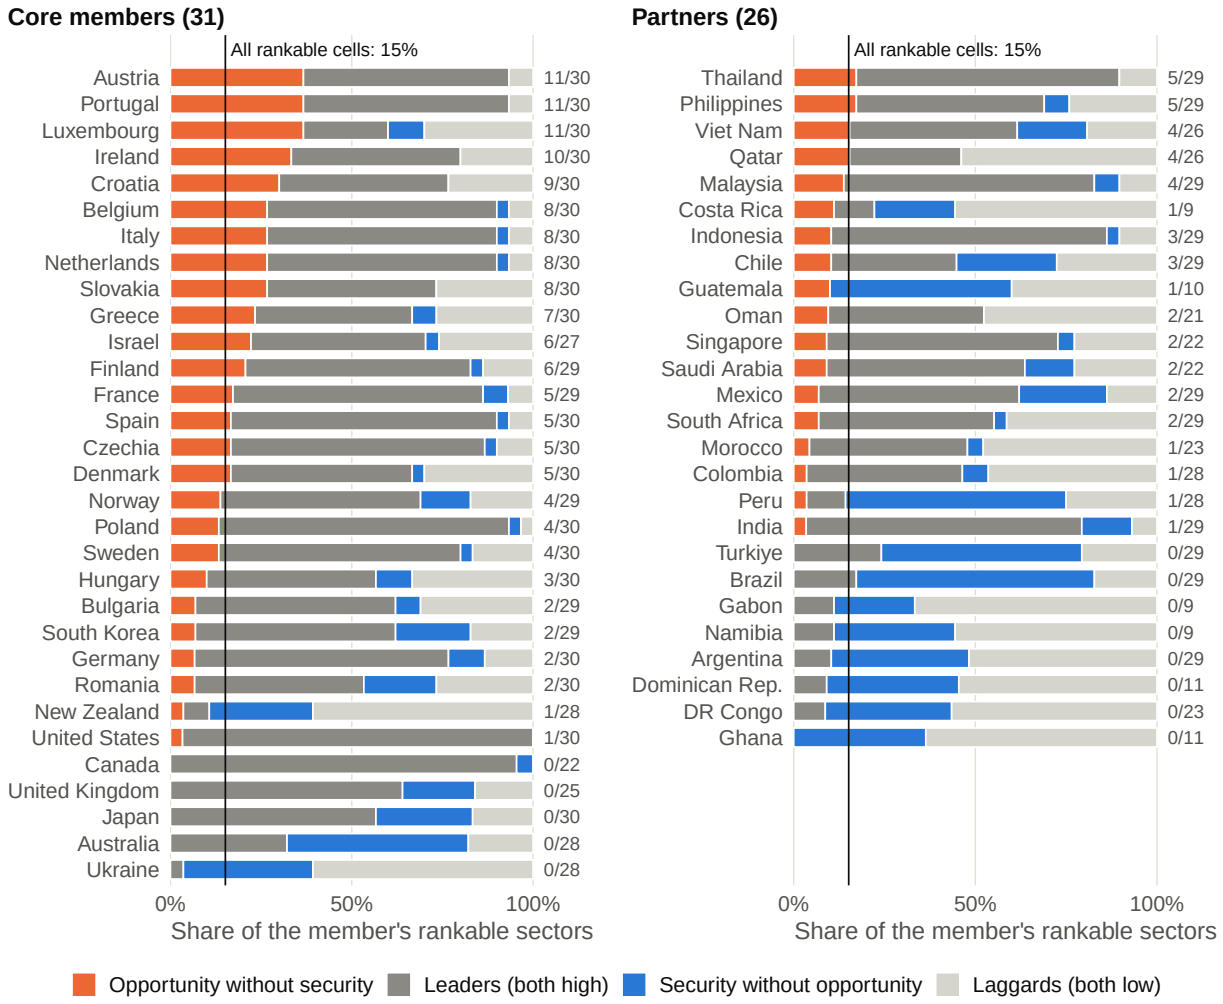

Figure 21: Each coalition member's rankable pairs divided among the four regions: the 31 core members (left) and 26 partners (right), ordered by the share with opportunity but not security; the fraction gives that count over the member's rankable pairs (9 to 30). The vertical line is the all-cell share (15 per cent). Nuclear upstream and Green Hydrogen midstream account for 25 of the 192 member pairs in orange. Source: as Figure 18.

8 Geopolitical alignment and the allied coalition

Three parts of the analysis need a coalition: the allied picks of the Strategic Index (Section 9), the viewpoint from which the Partnership Strength Index rates partners (Section 10) and the demand scope of the Allied Industrial Base analysis (Section 11). We derive it by rule from two observable attributes, an economy's alignment in the United Nations General Assembly and its weight in world supply, rather than fixing it by hand.

8.1 Ideal points and the U.S.–China axis

Alignment is measured with the ideal points of Bailey et al. (2017), which place every voting state on one dimension of revealed foreign-policy preference, bridged so that positions are comparable across sessions. We use the all-votes series of the July 2026 release (Dataverse V39; Voeten, 2009) and average each economy's ideal point θ_i over sessions 74 to 78 (2019–2023), which covers the 193 economies that vote in their own right. Each is placed on the segment between the two anchors,

$$s_i \;=\; \min\Big\{1,\; \max\Big\{0,\; \frac{\theta_i - \theta_{\mathrm{CHN}}}{\theta_{\mathrm{USA}} - \theta_{\mathrm{CHN}}}\Big\}\Big\}, \tag{50}$$

so that $s_i = 0$ is China's position and $s_i = 1$ that of the United States ($\theta_{\mathrm{USA}} = 2.34$, $\theta_{\mathrm{CHN}} = -1.02$). Seven economies vote further from the United States than China does and are clamped to zero (Cuba, Iran, Nicaragua, North Korea, Syria, Venezuela and Zimbabwe). The axis records revealed preferences relative to two anchors, not alliance or any bilateral relationship.

Following Gopinath et al. (2025), blocs are quartiles of the axis: the U.S.-leaning bloc is the quarter of voting economies closest to the United States ($s_i \geq 0.511$, 49 economies), the China-leaning bloc the quarter closest to China ($s_i \leq 0.142$, 49), and the 95 in between are nonaligned. Membership is hard: the bloc indicator p_i is 1 for U.S.-leaning, $\frac{1}{2}$ for nonaligned and 0 for China-leaning economies. Because the United States often votes in small minorities, the distribution is skewed toward China (median $s = 0.22$), and a midpoint rule would call 142 of 193 economies China-leaning; quartiles keep that bloc to the quarter of the Assembly closest to China. After the cuts are set, 44 territories inherit their sovereign's bloc and Taiwan, Palestine and Kosovo are neutral ($p_i = \frac{1}{2}$); these assignments serve only the bilateral indices, and an economy without its own vote cannot be a core member.

For a pair of economies the dyadic alignment is

$$A_{ij} \;=\; p_i\, p_j + (1 - p_i)(1 - p_j), \tag{51}$$

which would be the probability that i and j fall on the same side of the divide if p_i were a probability; with hard blocs it is 1 for the same bloc, 0 for opposite blocs and $\frac{1}{2}$ whenever either is nonaligned. It is a Friendshore component with weight 2 of 11 (Section 10.2) and through Friendshore enters the ranking of investment hosts in the Allied Industrial Base analysis. Figure 22 shows the axis by coalition tier.

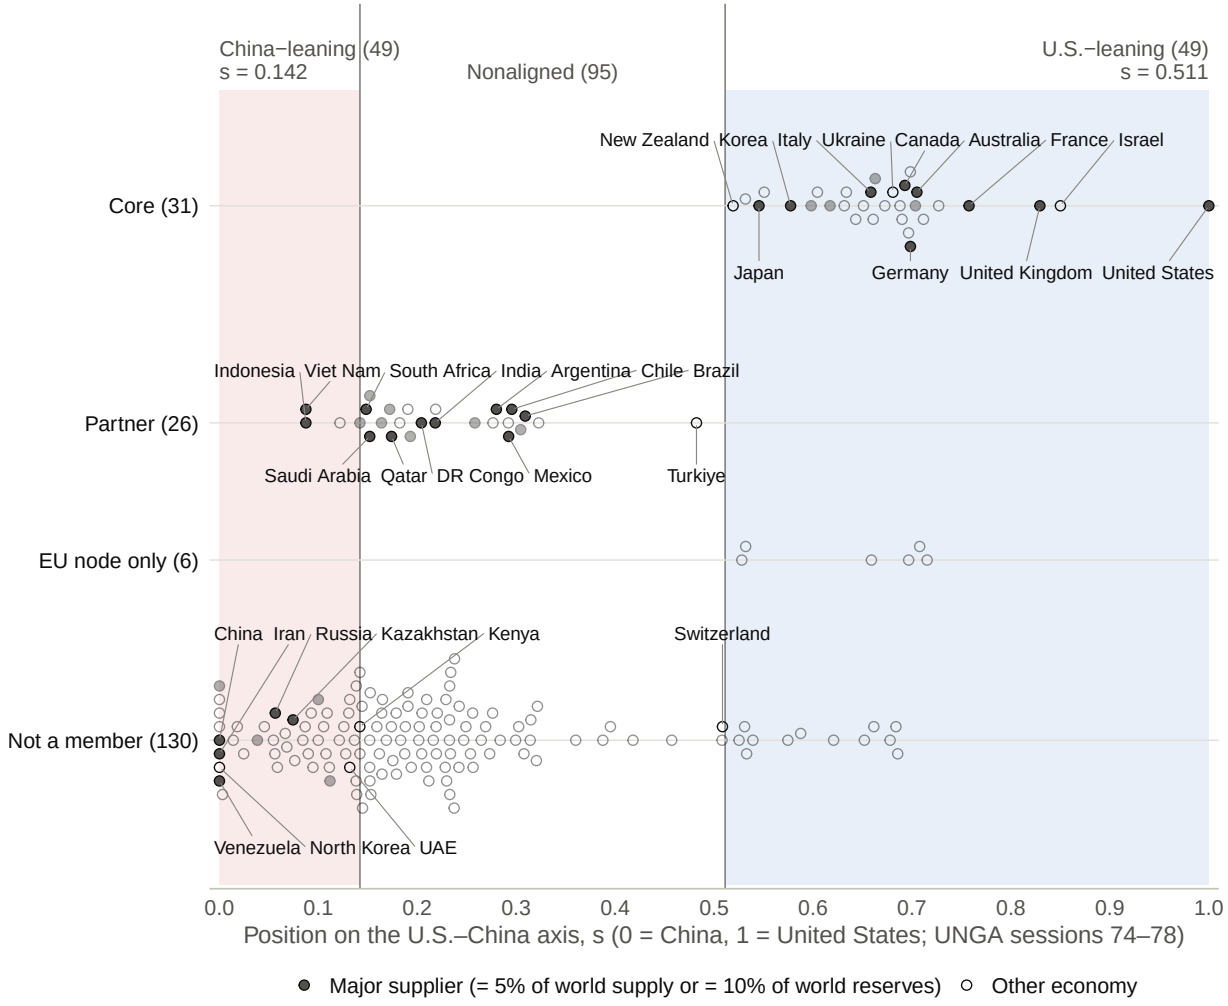

Figure 22: Positions on the U.S.–China axis and coalition tiers. Each point is one of the 193 economies with their own votes in the General Assembly, at s_i of equation (50): the mean all-votes ideal point of Bailey et al. (2017) over sessions 74–78 (2019–2023), projected on the segment from China ($s = 0$) to the United States ($s = 1$) and clamped to $[0, 1]$. Vertical lines are the quartile cuts ($s \leq 0.142$ China-leaning, $s \geq 0.511$ U.S.-leaning; 49, 95 and 49 economies). Rows are the 31 core members, the 26 partners, the six EU members below the GDP floor and the 130 other voting economies; vertical position within a row carries no information. Filled markers are major suppliers (at least 5 percent of world supply in an Upstream or Midstream stage, or at least 10 percent of world reserves of a headline mineral, fuel or uranium). G20 economies and selected other cases are labelled. Source: `geo_ideal_points_tbl.rds`, `coalition_tbl.rds`, `major_supplier_shares_tbl.rds`.

8.2 A coalition in two tiers

The *core* of the coalition $\mathcal{N}$ is the U.S.-leaning bloc restricted to economies with their own UN votes and a GDP of at least USD 100 billion (2025; World Bank, 2026): 31 economies. An economy outside the core is a *partner* if it qualifies by either of two routes. The agreement route admits members of a U.S. free trade agreement, the Indo-Pacific Economic Framework (IPEF), the Minerals Security Partnership (MSP), the G7 or NATO with GDP of at least USD 100 billion, whatever their bloc. The supplier route admits, without a GDP floor, any economy that is not China-leaning and is a major supplier of an Upstream or Midstream stage of a headline technology: it holds at least 5 percent of world supply in one measure of the stage (exports of the stage's HS6 basket, fuel or uranium production, mineral mining or refining, or manufacturing capacity), or at least 10 percent of world reserves of a resource the stage extracts, read from the reserves tables of the Energy Security pillar (U.S. Geological Survey, 2026; Energy Institute, 2026; OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026). The reserves bar is twice the supply bar because a stock is not yet supply; holders that USGS does not quantify count as zero. Online Appendix OA.6 lists the source and year of each measure.

The rule yields 26 partners (Table 15, Figure 23): ten qualify through agreements only, nine as suppliers only and seven by both routes. Twenty-three are nonaligned and three China-leaning: Indonesia and Viet Nam, members of IPEF, and Oman, a U.S. free-trade partner. The 57 members account for 73.4 percent of world GDP (core 57.7, partners 15.7); China accounts for 16.6 percent.

Forty economies pass the supplier test, and every one that is not China-leaning is a member. The nine China-leaning major suppliers are kept out: China, Russia, Iran, Kazakhstan, Algeria, Uzbekistan, Venezuela, Myanmar and Zimbabwe, with largest qualifying shares from 94.4 percent of world graphite refining (China) and 45.1 percent of exports of the uranium basket (Kazakhstan) to 5.1 percent of gas exports (Algeria). Eleven members hold at least 10 percent of a world reserve (Indonesia, China-leaning, cannot use the supplier route), and for none of the other ten is the reserves leg decisive. Brazil, in none of the five agreements, holds 23.9 percent of world graphite reserves, 16.7 percent of manganese, 14.6 percent of rare earths and 11.4 percent of nickel, and also supplies 18.4 percent of world exports of silicon metal (the Solar Upstream basket). Among all economies the reserves leg is decisive only for Venezuela, which is kept out.

Two economies a reader might expect are not members. Switzerland is nonaligned at $s = 0.508$, three thousandths below the U.S.-leaning cut, belongs to none of the agreements, and its largest supply share is 1.1 percent; its former supplier route rested on electricity exports, no longer part of the Electric Grid basket (Section 3). Taiwan has no UN vote and is therefore neutral, appears in no agreement list and has no World Bank GDP; its largest share is 1.5 percent (Solar Midstream exports), and its semiconductor strength lies outside the energy baskets. Both remain partners in the bilateral indices and candidate suppliers in the Allied Industrial Base analysis, but are not members.

The coalition is long in mining and short in processing: its economies mine 81.9 percent of the world's cobalt and 60.0 percent of its lithium but refine 17.4 and 24.6 percent, and 5.5 percent of

Table 15: Composition of the allied coalition

Group	n	Economies
Core: U.S.-leaning bloc, GDP $\geq$ USD 100bn	31	United States, Germany, Japan, United Kingdom, France, Italy, Canada, Spain, Korea, Australia, Netherlands, Poland, Belgium, Ireland, Sweden, Israel, Austria, Norway, Denmark, Romania, Czechia, Portugal, Finland, Greece, New Zealand, Hungary, Ukraine, Slovakia, Bulgaria, Croatia, Luxembourg
Partners, agreement route only	10	Türkiye (NATO), Indonesia (IPEF), Singapore (IPEF, U.S. FTA), Thailand (IPEF), Viet Nam (IPEF), Morocco (U.S. FTA), Dominican Rep. (U.S. FTA), Guatemala (U.S. FTA), Oman (U.S. FTA), Costa Rica (U.S. FTA)
Partners, supplier route only	9	Brazil (Solar Up 18% [+3]), Saudi Arabia (Oil Up 13%), Argentina (Batteries Up 6% [+1]), South Africa (Hydrogen Up 52% [+3]), Qatar (Gas Up 14%), Ghana (Batteries Up 10% [+2]), DR Congo (Batteries Up 66% [+9]), Gabon (Batteries Up 25% [+2]), Namibia (Nuclear Up 12%)
Partners, both routes	7	India (IPEF, MSP), Mexico (U.S. FTA), Philippines (IPEF), Malaysia (IPEF), Colombia (U.S. FTA), Chile (U.S. FTA), Peru (U.S. FTA)
EU members in the EU node only	6	Lithuania, Slovenia, Latvia, Estonia, Cyprus, Malta
Major suppliers kept out (China-leaning)	9	China (Batteries Mid 94% [+16]), Russia (Hydrogen Up 29% [+6]), Iran (Gas Up 6% [+1]), Kazakhstan (Nuclear Up 45%), Algeria (Gas Up 5%), Uzbekistan (Nuclear Up 8%), Venezuela (Oil reserves 18%), Myanmar (Wind Up 31% [+1]), Zimbabwe (Batteries Up 9% [+2])
Reserves holders between 5% and 10%, not members	6	Madagascar (Graphite 8.7%), Mozambique (Graphite 8.1%), Kuwait (Oil 5.9%), Tanzania (Graphite 5.8%), Niger (Uranium 5.7%), New Caledonia (Nickel 5.1%)
Added by the MSP Forum sensitivity	3	Kazakhstan, Uzbekistan, Ecuador
Hand-picked list of the previous draft: not members	2	UAE, Kenya
Hand-picked list of the previous draft: members	21	11 in the core, 10 partners

Notes: Economies are ordered by GDP within a group. Core: the U.S.-leaning quartile bloc of the all-votes ideal points of Bailey et al. (2017) over UNGA sessions 74–78 (2019–2023), $s \geq 0.511$, with the economy's own UN votes and latest World Bank GDP of at least USD 100bn. Partners (not core): a member of a U.S. free trade agreement, IPEF, the Minerals Security Partnership (MSP), the G7 or NATO with GDP of at least USD 100bn (qualifying agreements in parentheses), or, without a GDP floor, an economy that is not China-leaning and holds at least 5% of world supply in one measure of an Upstream or Midstream stage of a headline technology (exports of the stage's HS6 basket, fuel or uranium production, mineral mining or refining, or manufacturing capacity) or at least 10% of world reserves of a headline mineral, fuel or uranium. For the supplier route, the parentheses give the largest qualifying share: the technology–stage cell of a supply measure, or the resource when only reserves qualify, and in brackets the number of further qualifying cells. The six EU members below the GDP floor belong to the coalition only through the EU. The MSP Forum sensitivity admits Forum members by the agreement route. The previous draft's 23 members were fixed by hand.

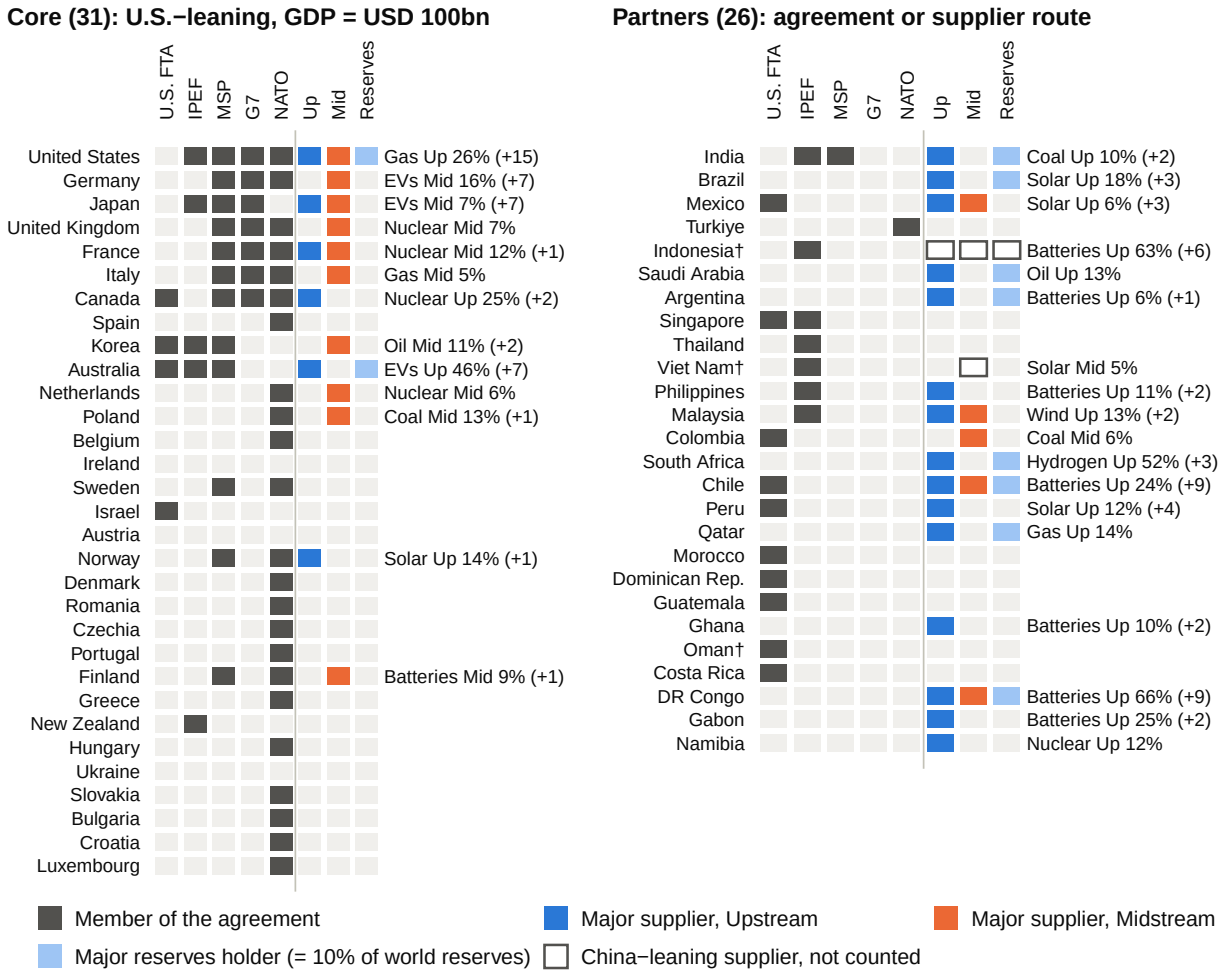

Figure 23: Routes into the coalition. Rows are the 31 core members (left) and the 26 partners (right), ordered by GDP. Gray tiles mark membership of the five agreements of the agreement route (U.S. free trade agreement, IPEF, MSP, G7, NATO). Coloured tiles mark the supplier test: at least 5 percent of world supply in an Upstream (blue) or Midstream (orange) stage, or at least 10 percent of world reserves (light blue). Outlined tiles (†) mark economies that pass the test but are China-leaning and so cannot use the supplier route; Indonesia and Viet Nam enter through IPEF and Oman through its U.S. free trade agreement. The core requires neither route. The text gives the largest qualifying share, with the number of further qualifying cells in parentheses. Source: `coalition_tbl.rds`, `major_supplier_shares_tbl.rds`, `economic_security_agreements.csv`.

graphite, against China's 75.6, 73.7 and 94.4 percent (International Energy Agency, 2026a); Online Appendix OA.6 gives the supply cover by stage.

8.3 The European Union

The coalition table also represents the EU-27 as a single unit, because the Union conducts a common commercial policy and its members' supply chains are integrated in a single market. Twenty-one EU members are core members in their own right; the six below the GDP floor (Cyprus, Estonia, Latvia, Lithuania, Malta and Slovenia, 1.6 percent of EU GDP) belong to the coalition's 63 economies only through the Union. With the EU as one unit the coalition has 37 units: 11 core (the United States, the EU, Japan, the United Kingdom, Canada, Korea, Australia, Israel, Norway, New Zealand and Ukraine) and 26 partners. Earlier drafts allocated production among these 37 units in a network design that the paper no longer uses (Appendix D). The Allied Industrial Base analysis of Section 11 treats each EU member as an economy in its own right, so that trade among members is part of both the demand it protects and the response it measures; the six members below the floor are outside its demand scope but may supply it.

8.4 Alignment within the coalition

Because the blocs are hard, alignment within the coalition takes a simple form (Figure 24). Of the 666 pairs of the 37 coalition units, 8.7 percent have $A_{ij} = 1$ (pairs of core nodes and pairs among the three China-leaning partners), 86.3 percent have $A_{ij} = \frac{1}{2}$ because one of the two is a nonaligned partner, and 5.0 percent have $A_{ij} = 0$: each core node paired with Indonesia, Viet Nam or Oman. The alignment component of Friendshore thus separates core from partner-tier members and penalises the three China-leaning partners as friendshoring partners of the core, but leaves the ordering of the 23 nonaligned partners to the other components.

8.5 Sensitivity and comparison with the hand-picked list

Two alternative vote series test the axis. With session 78 alone the Spearman correlation of s with the headline is 0.966, 89.1 percent of economies keep their bloc and the coalition keeps 57 members, with three changes at the margin. With the final-passage series over sessions 76–80 (2021–2025) the correlation is 0.965 and the core is unchanged, but the China-leaning cut falls to 0.055: Russia, Kazakhstan and Myanmar leave the China-leaning quartile and would enter as major suppliers, for 60 members. The core is robust to the vote series; the exclusion of China-leaning suppliers is the fragile element of the rule. Admitting the MSP Forum as a further agreement adds Kazakhstan, Uzbekistan and Ecuador.

The derived coalition replaces a list of 23 economies fixed by hand in an earlier version (Appendix D). Twenty-one remain; the United Arab Emirates and Kenya, both China-leaning, in no agreement and without a qualifying share, leave; 36 economies join.

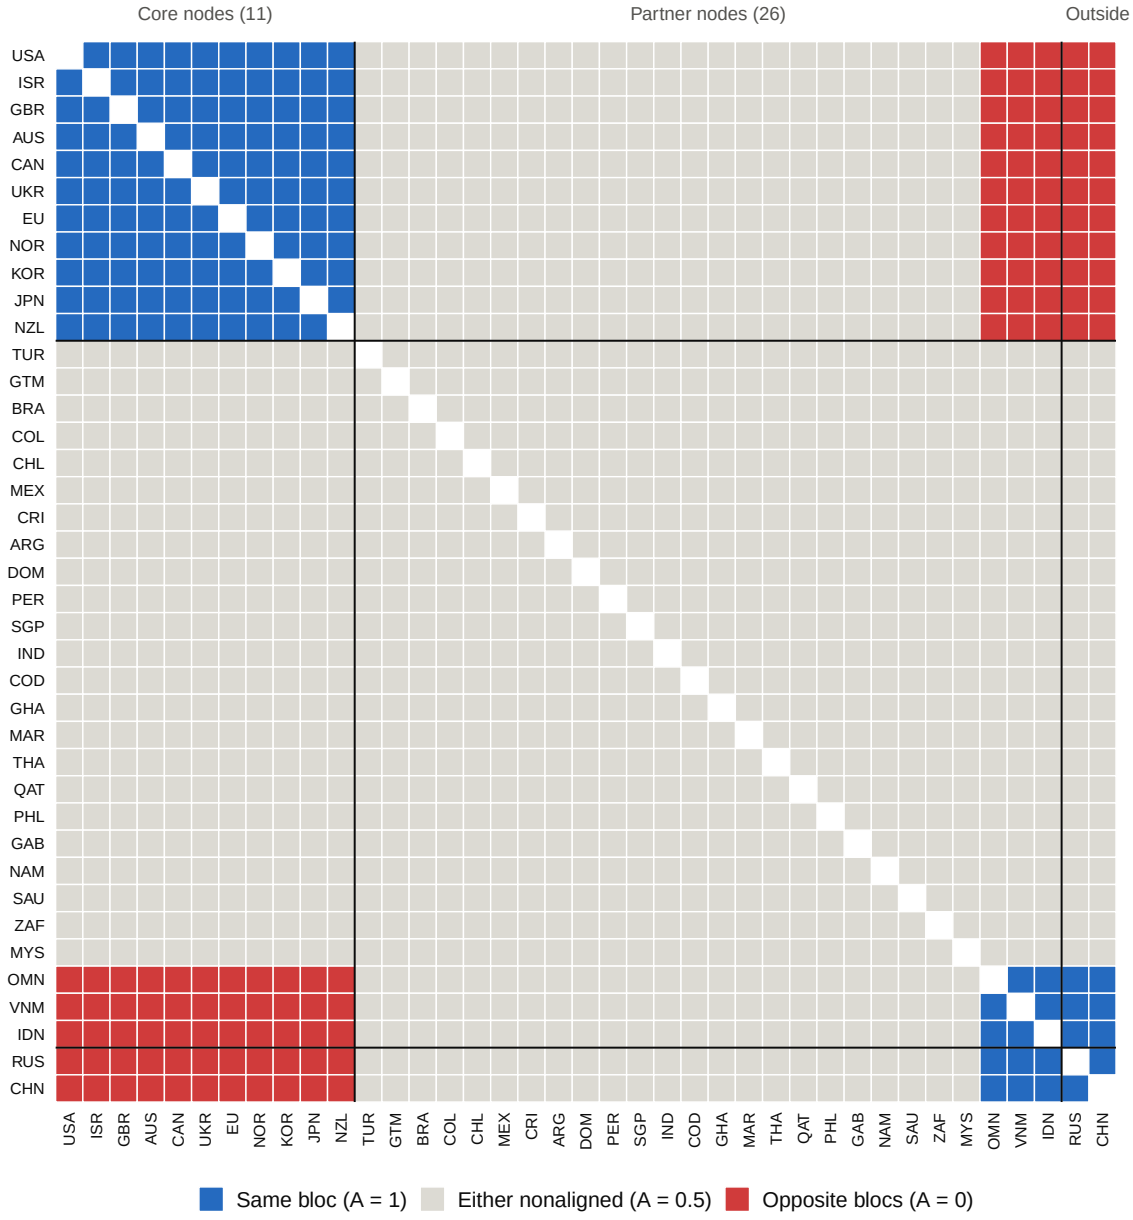

Figure 24: Dyadic alignment among the 37 coalition units, with the EU-27 as one. Each cell is A_{ij} of equation (51): 1 for the same bloc, 0 for opposite blocs and $\frac{1}{2}$ when either economy is nonaligned. The 37 units, 11 core and 26 partner, are followed by Russia and China for reference, ordered by tier and, within a tier, by s (for the EU, the GDP-weighted mean of its members, 0.677; all 27 members are U.S.-leaning). Source: `geo_alignment_tbl.rds`, `allied_network_nodes.csv`.

The rule and a functional definition of "allied". The working paper on the Allied Industrial Base (New Energy Industrial Strategy Center, 2026) argues that "allied" should be a functional rather than a treaty category, with partners assessed on reliability and contractual performance, economic complementarity, strategic alignment, burden sharing, technology-security requirements and contribution to system resilience, and with membership varying across sectoral compacts. The derived coalition implements part of that programme: the axis measures strategic alignment, the supplier route contribution to world supply and reserves, and the agreement route economic-security ties with the United States that are already institutionalised. It does not measure reliability, the rule of law, burden sharing or technology-security requirements, and it defines one coalition for all 22 stages. The supplier route gives the boundary a sectoral margin (nine partners qualify only as suppliers of particular stages), but a coalition defined stage by stage, admitting a resource holder to a minerals compact without admitting it to one on sensitive grid equipment, is left to future work.

9 The Policy index and the Strategic Index

This section constructs a Policy index POL_{its} of recorded policy activity in each cell and a Strategic Index SI_{its} that combines it with the two pillars and two fixed sector weights into a ranking of each country's sectors, from which one allied pick is drawn for each coalition member. Both have normative weights (Nardo et al., 2008; Decancq and Lugo, 2013); we state each and report the choices to which the rankings are sensitive.

9.1 The Policy index

No measure of industrial policy captures whether a policy is well designed (Juhász et al., 2024, 2022; Evenett et al., 2024). The Policy index measures the intensity and direction of state attention to a cell, which indicates where capacity is likely to be built and sustained (Rodrik, 2004, 2014), not whether that attention is warranted. It has two components.

IEA Policies and Measures. The IEA database records national, subnational and international energy and climate policies with their status, jurisdiction, type and text (International Energy Agency, 2026e). Each policy h is assigned to technologies and stages by keyword rules and given a strength σ_h, the product of type, status and jurisdiction weights and of discounts for cross-cutting or text-only assignments. The component is the S-curve of the log summed strength, ranked over all country–technology–stage cells jointly so that it keeps differences in policy density across countries and sectors,

$$x^{\mathrm{IEA}}_{its} = \phi_\gamma\Big[\log\Big(1+\textstyle\sum_{h\in\mathcal{H}_{its}}\sigma_h\Big)\Big]_{\mathrm{all}}. \tag{52}$$

Online Appendix OA.7 gives the tagging rules and weights.

Climate Action Tracker. The CAT component interacts a country's overall climate-policy rating, mapped to $\kappa_i \in \{0.25, 0.5, 0.75, 1\}$ (critically insufficient to almost sufficient; Climate Action

Tracker, 2026), with the technology weight g_t defined below,

$$x_{its}^{\text{CAT}} = \kappa_i \, g_t + (1 - \kappa_i)(1 - g_t) \qquad \text{for every stage } s. \tag{53}$$

Its slope in g_t is $2\kappa_i - 1$: a rating of "insufficient" or better tilts a country's cells toward clean technologies, "highly insufficient" leaves them flat and "critically insufficient" tilts them toward fossil ones (Figure 25, panel a). EU members without a rating of their own take the EU's.

Composite and eligibility. The Policy index is the weighted mean of the components observed in the cell,

$$\text{POL}_{its} = \frac{\sum_{v \in \mathcal{V}_{its}} \omega_v \, x_{its}^{v}}{\sum_{v \in \mathcal{V}_{its}} \omega_v}, \qquad (\omega_{\text{IEA}}, \omega_{\text{CAT}}) = (3, 2). \tag{54}$$

The IEA component is required and CAT is added where the Tracker rates the country. All 215 economies in the IEA database receive an index: 65 on both components and 150 on the IEA component alone, with the basis recorded. Requiring both components, the rule until October 2026, is a robustness variant.

Why NIPO and the dual-use score are excluded. Earlier versions of the composite also carried the New Industrial Policy Observatory of Global Trade Alert (NIPO; Global Trade Alert, 2026; Evenett et al., 2024), with weight 4, and a dual-use score, with weight 1. The dual-use score is a project-authored judgement of each sector's defence relevance, identical for every country: it measures no country and would act as a further sector prior read as policy. NIPO is the most direct measure of industrial policy, but its allocation through product codes reaches only Upstream and Midstream cells, which changed the effective weights by stage, and the component available when the composite was fixed covered 23 economies. It returns as a robustness variant built from the October 2026 run (77 jurisdictions; Online Appendix OA.7).

9.2 The Strategic Index

For a cell in the sample, the index is

$$\text{SI}_{its} = 0.2 \, \text{POL}_{its}^{*} + 0.3 \, \text{EO}_{its} + 0.3 \, (1 - \text{ES}_{its}) + 0.1 \, \lambda_s + 0.1 \, g_t, \tag{55}$$

where the policy term is the within-country S-curve of the Policy index over the country's in-sample sectors,

$$\text{POL}_{its}^{*} = \phi_\gamma\big[\text{POL}\big]_i \qquad \text{over } \big\{(t', s') : \ (i, t', s') \text{ in the sample}\big\}, \tag{56}$$

and EO_{its} and ES_{its} enter at their cross-country levels. Every term lies in $[0, 1]$ and the weighted terms add up to the index exactly.

Policy, need and scaling. The policy term rewards the sectors on which a government already concentrates its attention, where programmes and administrative capacity make further effort more

likely to succeed (Rodrik, 2004; Juhász et al., 2024). It is ranked within the country because the volume of recorded policy depends on governments' transparency and compilers' attention; the pillars keep their cross-country levels, so that a sector in which a country leads the world counts for more than one in which it is merely its own best. Security enters as need, $1 - \mathrm{ES}_{its}$: new capacity is most valuable where it reduces an exposure rather than duplicating a strength (Section 2); the strength reading is reported below. Nominal weights are not effective weights (Paruolo et al., 2013; Becker et al., 2017), and the index ranks sectors within a country rather than comparing levels across countries.

Fixed sector weights. The stage weights are $\lambda_{\text{Midstream}} = 0.75$, $\lambda_{\text{Upstream}} = 0.5$ and $\lambda_{\text{Downstream}} = 0.25$: clean-energy supply chains are most concentrated in processing and manufacturing (International Energy Agency, 2021, 2024), extraction is bound to geology and deployment is largely non-traded. The technology weight g_t is a min-max index of lifecycle greenhouse-gas intensity. With c_r the median intensity ($\mathrm{gCO_2e/kWh}$) of generation technology r and R_t the rows of technology t,

$$g_t = \frac{1}{|R_t|} \sum_{r \in R_t} \frac{\max_{r'} c_{r'} - c_r}{\max_{r'} c_{r'} - \min_{r'} c_{r'}} \in [0, 1], \tag{57}$$

from the AR5 lifecycle medians (Schlömer et al., 2014) and, for oil-fired generation, the SRREN median of 840 $\mathrm{gCO_2e/kWh}$ (Moomaw et al., 2011); technologies without a row take proxies (Online Appendix OA.7). The weight runs from 0 for oil, 0.02 for coal and 0.42 for gas to 0.97 for solar and 0.999 for nuclear and wind. The two weights add a sector prior of 0.025 (Oil Downstream) to 0.175 (Wind Midstream) to every country's index (Figure 25, panel b): a stated preference for clean, midstream activity, not a measurement, which decides the ranking where a country's measured terms are flat. The same g_t scales the climate penalty of the bilateral indices (Section 10).

Implicit sector priors. Because the pillars enter at their cross-country levels, two further sector-level terms act as priors in each country's ranking, in addition to the stage and technology weights. Inputs that are the same for every economy in a pair (world demand, market size and overcapacity, TRL, price volatility and the world-concentration terms of Trade) shift that pair's pillar levels for all countries; on the scored cells they contribute on average 0.18 to EO_{its} and 0.07 to ES_{its}, and their net contribution to the index varies across sectors from -0.065 to 0.012. And stage-level differences in zero-inflation (in the median Upstream pair 71 percent of rankable economies score zero on Reserves; Section 5) lower Upstream security and so raise Upstream need for every country. The first term can be measured: across the 57 allied picks, the cell-constant inputs account for a median of 45 percent of the margin over the runner-up, favour the pick in 36 cases and exceed the whole margin in 18. Removing them from the pillar levels keeps 29 of the 57 picks, and entering opportunity and need as within-pair ranks keeps 27 (Section 12).

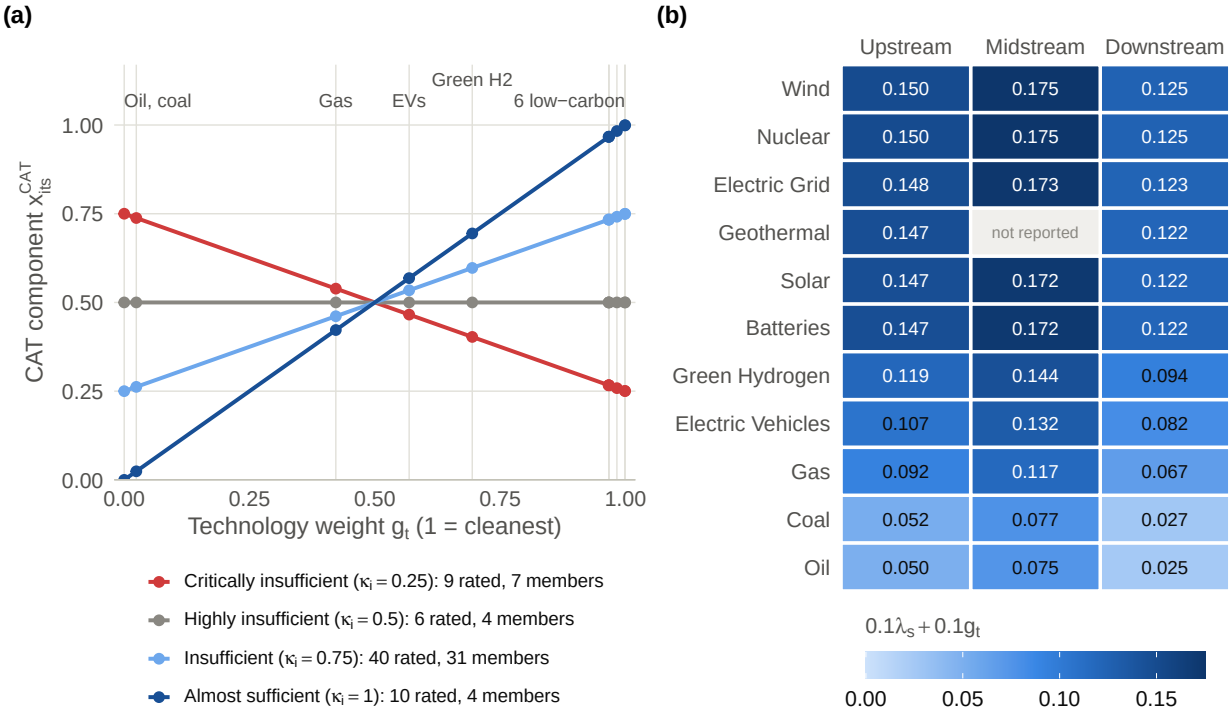

Figure 25: The country-invariant inputs of the Strategic Index. Panel (a): the Climate Action Tracker component of the Policy index, $x^{\mathrm{CAT}}_{its} = \kappa_i g_t + (1-\kappa_i)(1-g_t)$, against the technology weight g_t (IPCC life-cycle emissions, 1 = cleanest) for the four CAT ratings, with the eleven technologies marked on each line; the slope is $2\kappa_i - 1$. The legend counts the countries CAT rates in each category in the final build (65 in all, 26 of them EU members through the EU's rating) and the coalition members among them (46 of 57: 31 insufficient, 7 critically insufficient, 4 highly insufficient, 4 almost sufficient). Panel (b): the sector prior $0.1\lambda_s + 0.1g_t$ that the stage weights λ_s (Upstream 0.5, Midstream 0.75, Downstream 0.25) and the technology weights add to the Strategic Index of every country; Geothermal Midstream is not a reported sector. Source: the pipeline's functions and `data/raw/ipcc_ghg_intensity.csv`, with the CAT ratings of `policy_component_tbl` in `index_outputs.rds`; `scripts/paper/fig_si_fixed_inputs.R`.

9.3 Sample rules and the allied pick

Nothing is imputed in the Strategic Index. A cell is scored only if the country has a Policy index and both of its pillar cells are rankable under the rule of Section 4 (the economy is sovereign and at most half of each pillar cell's index weight is imputed); an unscored cell stays in the output with its reason recorded. Geothermal Midstream, which has no Energy Security pillar, is excluded by rule; a check that removes any sector whose pillar is constant across the scored countries finds none in the final build.

Allied pick. For each coalition member i, let $\mathcal{A}_i$ be its scored Upstream and Midstream sectors outside Geothermal and Green Hydrogen, less the Upstream sectors barred by the endowment screen below. The allied pick is

$$(t, s)_i^* = \arg\max_{(t,s)\in\mathcal{A}_i} \ \mathrm{SI}_{its}. \tag{58}$$

Only the traded stages, which coalition supply chains can organise across borders, are eligible; Geothermal and Green Hydrogen have no HS6 basket and Midstream Energy Security pillars that are constant or concentrated at one value. The pick summarises the index for each member, EU members included; the Allied Industrial Base analysis does not use it.

Endowment screen. With security read as need, an economy without a resource sits at the floor of the extraction stage's Energy Security pillar and has maximal need there. The screen makes an Upstream stage eligible for a member's pick only if the member has recorded reserves or production of the stage's resources (technology-level Reserves or Production greater than zero). It is a rule of the pick, not of the index: values are unchanged and screened cells are flagged.

9.4 Results

Coverage and basis of the Policy index. All 57 coalition members have a Policy index, 46 on both components and 11 on the IEA component alone: Israel and Ukraine in the core and nine partners (the Democratic Republic of the Congo, the Dominican Republic, Gabon, Ghana, Guatemala, Malaysia, Namibia, Oman and Qatar). The two components measure different things (Figure 26): over the 65 economies scored on both, their Spearman correlation is -0.05 across cells and -0.02 within a country at the median, and the composite follows the Tracker component within a country (median 0.79) more than the IEA one (0.48). Ranking these countries' cells on the IEA component alone gives a median within-country Spearman of 0.48 with the composite over their policy cells and 0.44 over their Strategic Index cells: the basis matters for a country's internal ranking.

Sample and distribution. The Strategic Index covers 3,154 cells of 174 countries in 30 sectors (Electric Grid Downstream and Geothermal Upstream have no scored cell). Of the 6,476 cells of policy-eligible countries, 2,700 fail the rankability rule on one or both pillars and 622 lack an Energy

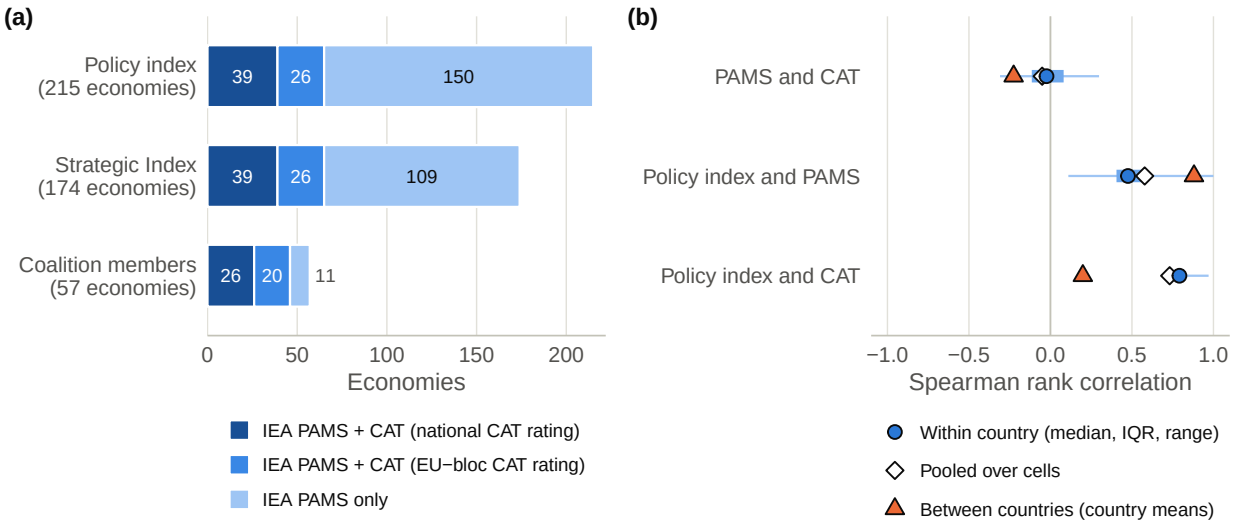

Figure 26: The basis of the Policy index. Panel (a): number of economies by the components of their Policy index, for all economies with an index (215), the economies with a Strategic Index cell (174) and the coalition members (57). "IEA PAMS + CAT" combines the IEA Policies and Measures database (weight 3) with the Climate Action Tracker rating (weight 2), national or, for EU members, the Union's; "IEA PAMS only" marks economies the Tracker does not rate. Panel (b): Spearman correlations among the two components and the composite over the 33 cells of the 65 economies scored on both: median, interquartile range and range of the within-country correlations (59 economies whose Tracker component varies across cells), pooled over cells and across country means. Source: `policy_component_tbl`, `policy_index` in `index_outputs.rds`.

Security cell. Every coalition member is scored, with a median of 29 sectors. The index (mean 0.535, standard deviation 0.082) is organised by sector far more than by country: sector fixed effects explain 72.6 percent of its variance and country fixed effects 4.4 percent (Figure 27). The highest cells are Nuclear Upstream cells of small economies without uranium, where Energy Security sits at a floor shared by 86 of the 174 countries and need is maximal: Nuclear Upstream is the top sector of 62 countries, 55 of them without recorded uranium. This construction effect of the need reading motivates the endowment screen. Green Hydrogen Midstream (34 of 40 countries at one value), Green Hydrogen Downstream, Nuclear Downstream and Batteries Downstream also have floors; no allied pick lies in a floor cell.

Decomposition. The five terms account for 18.8 (policy), 27.6 (opportunity), 32.4 (need), 9.3 (stage) and 11.9 percent (technology) of the index level, but very different shares of its within-country variance: on average 40.7 percent for the technology weight, 34.1 percent for need and 32.0 percent for policy, against −1.4 percent for opportunity and −5.4 percent for the stage weight. Opportunity moves against need (median within-country Spearman of EO and $1 - \text{ES}$ −0.47, negative in 164 of 167 countries; −0.49 and negative for all 57 coalition members), because a country's strongest opportunities tend to be the sectors in which it is already secure; the two offset, and the ranking is set by the technology weight, need and the policy rank (Figure 28).

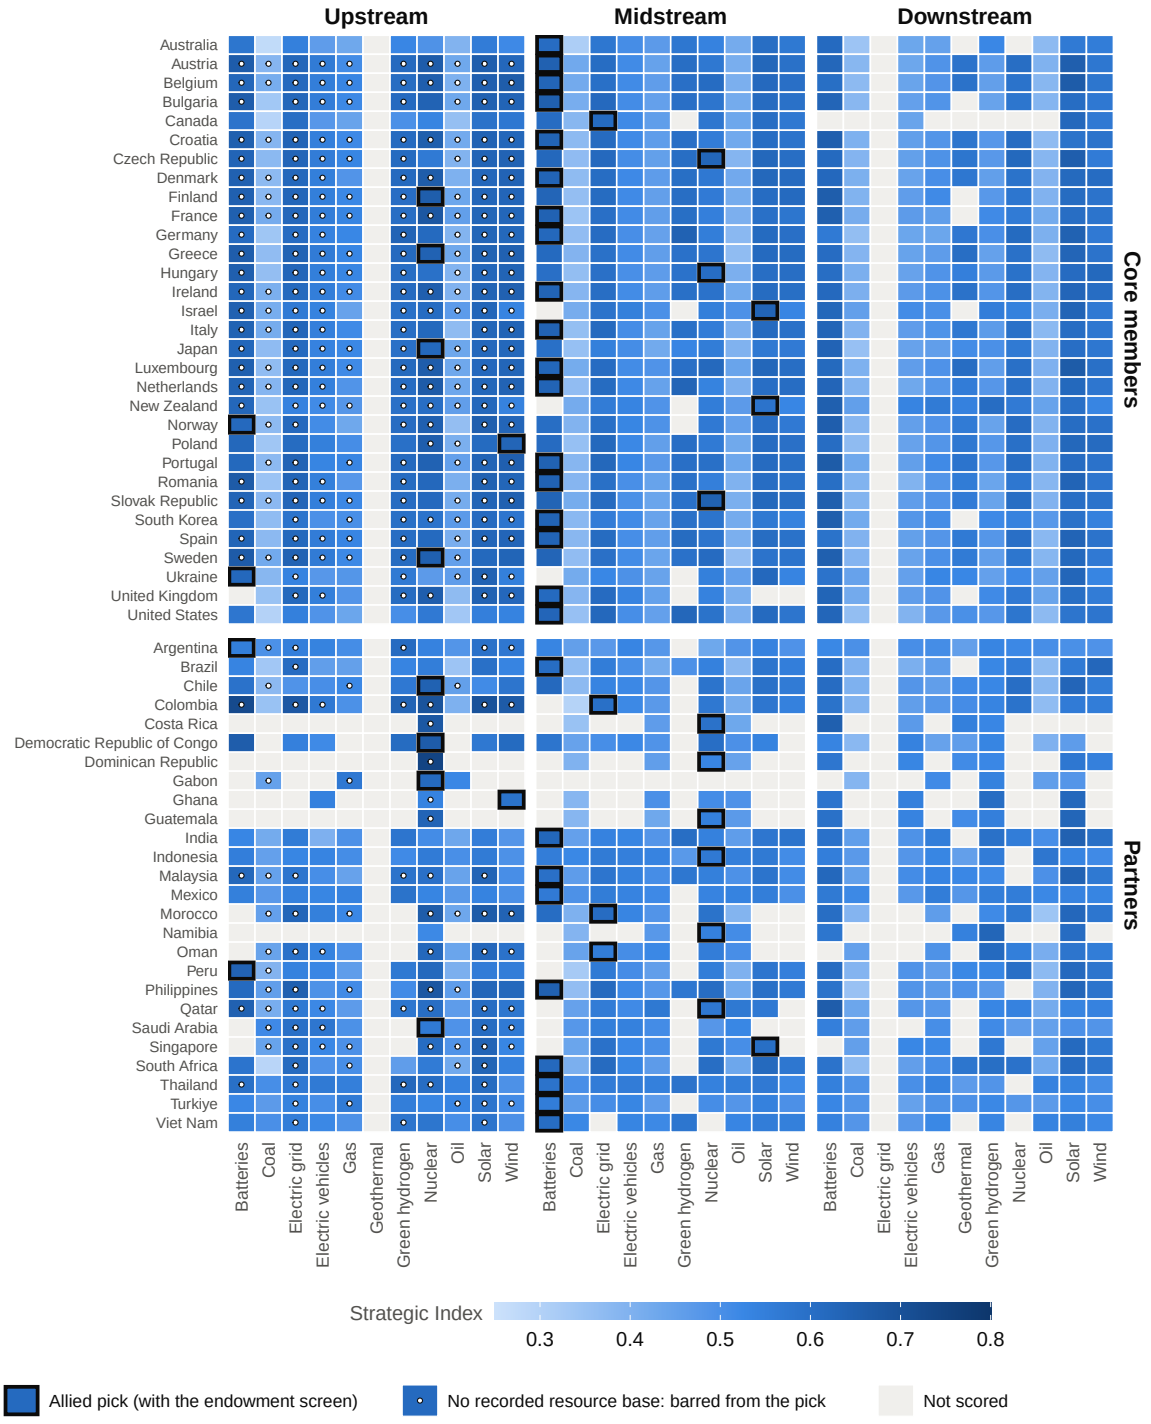

Figure 27: The Strategic Index across the coalition. Rows are the 57 members (31 core, then 26 partners), columns the 33 technology–stage cells grouped by stage; colour is SI_{its} (equation (55)). Grey cells are not scored (a pillar cell not rankable or missing, or Geothermal Midstream, excluded by rule). A dot marks an Upstream cell in which the member has no recorded reserves or production of the stage's resources: the endowment screen bars it from the pick, but its value is unchanged. The outlined cell in each row is the member's allied pick (equation (58)). Source: `strategic_index` in `index_outputs.rds`; `allied_strategic.csv`.

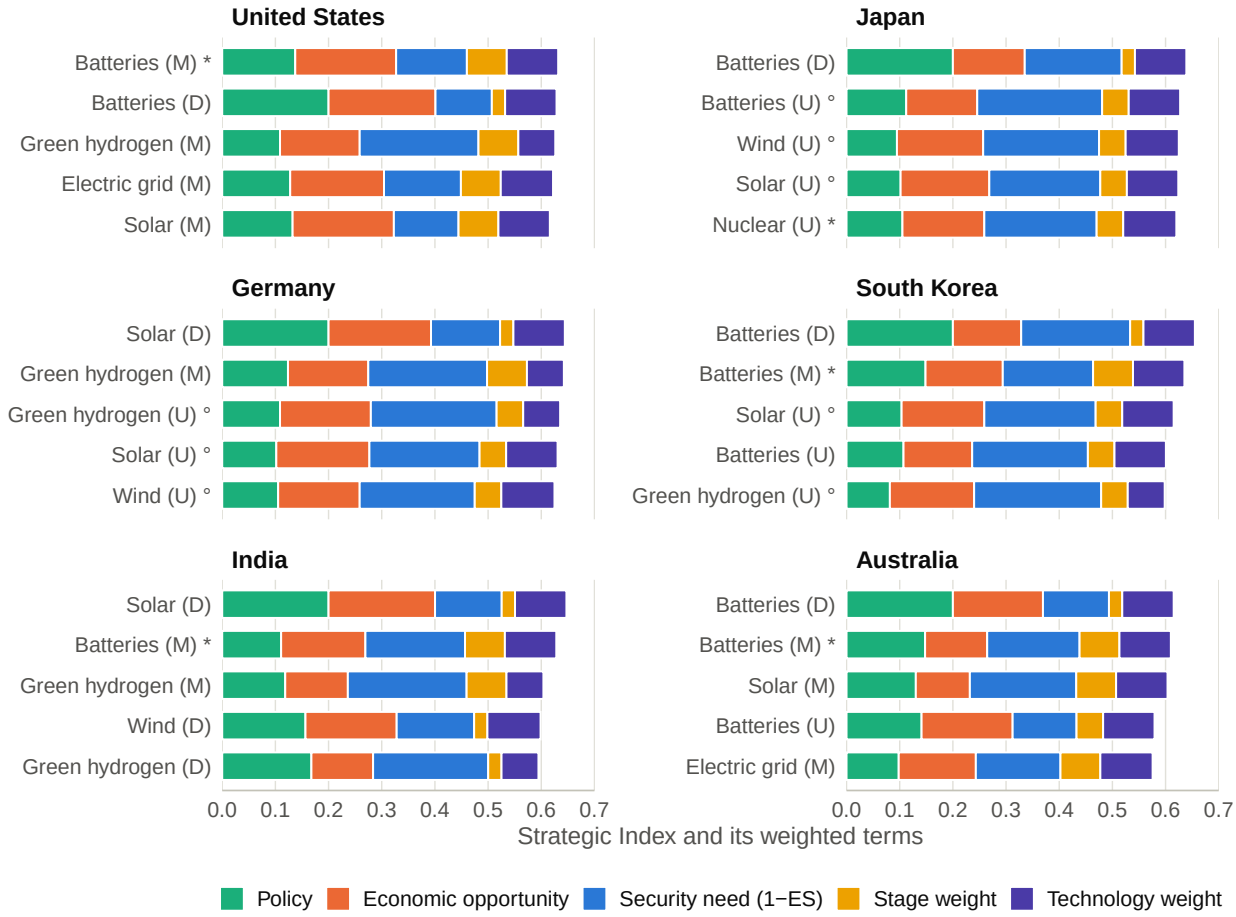

Figure 28: Decomposition of the Strategic Index for the five highest-ranked sectors of six coalition members. Each bar stacks the weighted terms of equation (55): $0.2\,\mathrm{POL}^{*}_{its}$, $0.3\,\mathrm{EO}_{its}$, $0.3\,(1-\mathrm{ES}_{its})$, $0.1\,\lambda_s$ and $0.1\,g_t$; bar length is SI_{its}. (U), (M) and (D) mark the stage; an asterisk marks the member's allied pick and a circle an Upstream sector barred by the endowment screen. Source: `strategic_index` in `index_outputs.rds`.

Allied picks. Every member has a pick, and none is tied (Table 16). Batteries Midstream is the pick of 27 members (among them the United States, Germany, Korea, India and Australia), Nuclear Midstream of nine, Nuclear Upstream of eight, Batteries Upstream and Electric Grid Midstream of four each, Solar Midstream of three and Wind Upstream of two (Ghana and Poland): 43 Midstream and 14 Upstream picks. The picks are sectors a member needs and supports with policy rather than sectors in which it already competes: within a member's eligible sectors the pick ranks first on policy for 22 members and on need for 23, but on opportunity for none. The eight Nuclear Upstream picks (Chile, the Democratic Republic of the Congo, Finland, Gabon, Greece, Japan, Saudi Arabia and Sweden) all hold identified uranium resources, but small ones, 0.015 to 0.79 percent of world identified resources below USD 260/kgU, and none has recorded mine production in 2019–2024. These picks are still need-driven: a negligible resource ranks near the floor of the security pillar, so the screen removes the no-resource artefact but not its small-resource counterpart. Requiring recorded production rather than any reserves removes all eight Nuclear Upstream picks (seven members move to another sector and Gabon is left without an eligible one) and the two Wind Upstream picks of Ghana and Poland.

The picks are fragile. The median margin over the runner-up is 0.015; it is below 0.005 for 10 members (17.5 percent) and below 0.01 for 21 (36.8 percent), against a within-country standard deviation of 0.080, so the table reports the runner-up beside each pick. The distribution also moved during the final data revisions: in a run of 8 October, when 45 members had a pick, Electric Grid Midstream was the pick of 17 and Batteries Midstream of 11, before completing the energy-trade file filled missing codes of the grid basket.

The Nuclear Midstream picks of small partners are not an Energy Security floor effect. Costa Rica, the Dominican Republic and Guatemala each have four eligible sectors, the Midstream stages of nuclear, oil, gas and coal (Namibia these and Nuclear Upstream). The technology weight ($g_t = 0.999$ for nuclear against 0.42 for gas, 0.02 for coal and 0 for oil) puts Nuclear Midstream's sector prior 0.058, 0.097 and 0.100 ahead of the three fuels, more than any other term separates pick from runner-up, while Nuclear Midstream Energy Security is compressed around its median (interquartile range 0.095, against 0.12–0.15 in the fossil Midstream sectors), so need adds only 0.020–0.042.

Picks and the Allied Industrial Base. The pick is a national priority read from need and policy, not an allied assignment. Aggregated, the picks reproduce the duplication that an Allied Industrial Base is meant to avoid: 27 members would prioritise Batteries Midstream. The stress test of Section 11 agrees that batteries are where the allies are most exposed, but it needs fewer countries and different ones. The four Sectoral Compacts with a Batteries Midstream node (the battery chain from cells to packs, battery packs, lithium chemicals with cathode materials, and anode materials with natural graphite) have 23 economies in their minimum coalitions, of whom 12 pick the stage. The other 15 pickers sit in none of these coalitions, while 11 economies in them do not pick it: eight members whose picks lie elsewhere (Canada, Chile, Hungary, Indonesia, Japan, Norway, Poland and Singapore) and three economies outside the coalition (Madagascar, Mozambique and Taiwan).

Across all members, 13 of the 57 sit in the coalition of a compact with a node in their pick stage (the column "AIB coalitions" of Table 16).

Members with the same pick (of 57)						16	5	31

Notes: For each coalition member with a Strategic Index, the pick is the Upstream or Midstream sector outside Geothermal and Green Hydrogen with the highest index (equation (58)), after the endowment screen bars Upstream sectors in which the member has no recorded reserves or production; the runner-up is the second-highest such sector and the margin the difference between their indices; (U) Upstream, (M) Midstream. No member has a tie. AIB coalitions counts the Sectoral Compacts of Section 11 with a node in the pick stage whose exact minimum coalition includes the member (– if none). "Pick without the screen" is the pick when the endowment screen is switched off ("same" if unchanged); the index values are the same in both cases. Columns (1) and (2) mark whether the pick, with the screen, is unchanged when the index is recomputed on the same cells (1) with security strength ES in place of need $1 - \text{ES}$ and (2) without the stage and technology weights. All 57 members have a pick. † Policy index on IEA PAMS alone (no CAT rating; 11 members); the other members' Policy index combines IEA PAMS and CAT. Source: `index_outputs.rds` and `allied_strategic.csv` of the final run, which the script reproduces; `scripts/paper/fig_strategic.R`.

The endowment screen. Of the 998 scored Upstream cells in the screened technologies, 669 have no recorded resource base (306 of the coalition's 509). The screen changes 41 of the 57 picks (Figure 29): without it 47 picks would be Upstream (Nuclear 17, Batteries 12, Solar 12, Wind 5 and Electric Grid 1), many in members without the resource, such as Nuclear Upstream for France and the United Kingdom. The index forgone is small for most members (median 0.026; largest for the Dominican Republic, 0.216). An economy cannot become an allied supplier of a resource for which it has no recorded reserves or production.

The security sign and other normative choices. Reading security as strength, ES in place of $1 - \text{ES}$, gives an index that agrees only weakly with the headline (Figure 30): the median within-member Spearman correlation is 0.36, only 5 of the 57 picks survive, and picks move to Nuclear Midstream (28), Gas Midstream (10) and Electric Grid Midstream (7). The sign is the most consequential normative choice: the need reading asks where an economy should build capability to reduce its exposure, the strength reading where it can build on capability it has. The other choices keep median within-member correlations of 0.88–0.96 but change many picks. Of the 57 members, 31 keep their pick without the stage and technology priors, 30 without the policy term, 20 when opportunity and need are ranked within the country, and 34 when the October 2026 NIPO component is added back (27 of the 50 members with NIPO data); policy from IEA PAMS alone keeps 45 (34 of the 46 members scored on both components). The headline pick stays in the variant's top three for 86 to 96 percent of members. Requiring both policy components removes the 11 members scored on the IEA component alone and leaves the other cells unchanged. A member's sector ordering is thus robust to these choices, but its single pick is not (Online Appendix OA.7; Section 12).

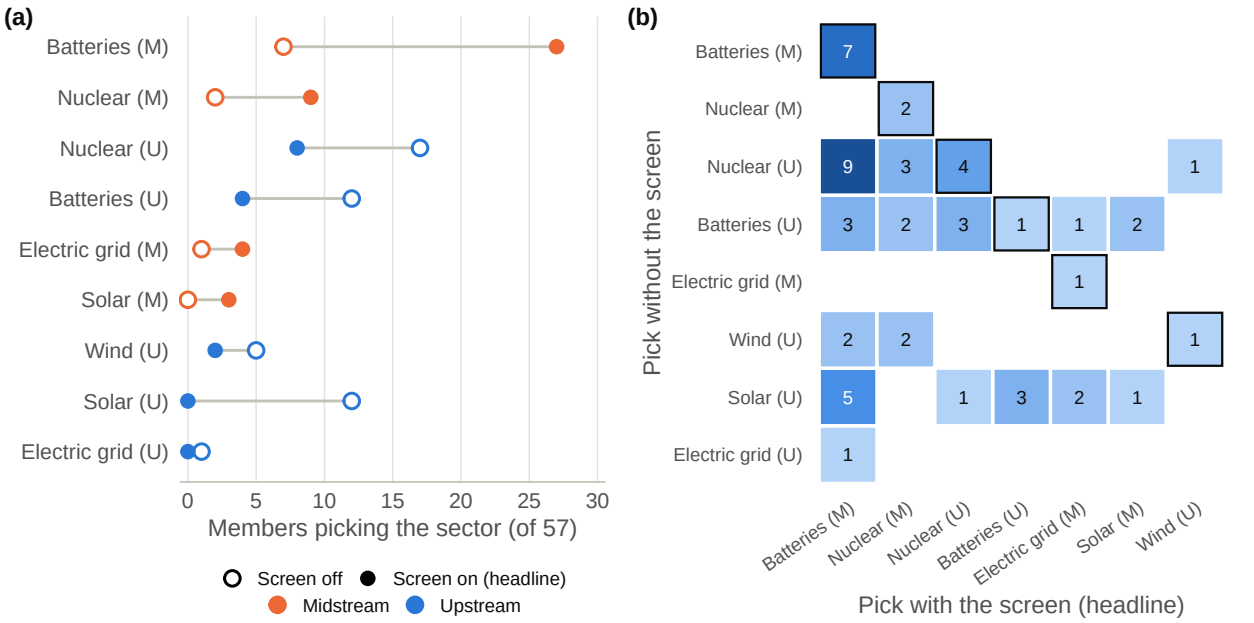

Figure 29: Allied picks with and without the endowment screen. Panel (a): number of the 57 members whose pick is each sector, with the screen (filled, the headline) and without it (open); colour is the stage. Panel (b): transition between the two selections; each tile counts the members whose pick without the screen is the row and with it the column; outlined diagonal tiles are unchanged picks (16 members). Index values are the same in both selections; the screened selection equals `allied_strategic.csv`. Source: `strategic_index` in `index_outputs.rds`; `select_allied_strategic_sectors()` with the screen on and off.

10 Bilateral partnership indices

Friendshoring trades the security of supply from trusted partners against the efficiency cost of narrowing the set of sources (Yellen, 2022; Aiyar et al., 2023; Gopinath et al., 2025; Javorcik et al., 2024; Grossman et al., 2023), and sourcing is already being reallocated across partners (Alfaro and Chor, 2023; Freund et al., 2024). Its unit is the pair of countries. This section builds three bilateral pillars and a composite: the *Friendshore* index FS scores partner j as a friendshoring opportunity for economy i in (t, s), a partner in which i could invest and from which it could source to meet its security need; the *Partnership Opportunity* index PO rates j as a market for i's exports; the *Development Potential* index DP rates j alone as a development partner; and the *Partnership Strength Index* PSI combines them (Table 17). The Allied Industrial Base analysis (Section 11) uses the dyad-level PO to order equally good trade allocations and FS to order capable investment hosts, not the PSI.

10.1 Dyads, trade and shared building blocks

A dyad (i, j, t, s) pairs reporter i and partner $j \neq i$, among 219 economies, in a headline technology t and stage s. In FS_{ijts} the reporter is the economy with the security need and j the candidate partner for its investment and sourcing; in PO_{ijts} the reporter is the exporter and j the candidate market. Both rate j from i's side, so a supply relationship from exporter or host e to importer m

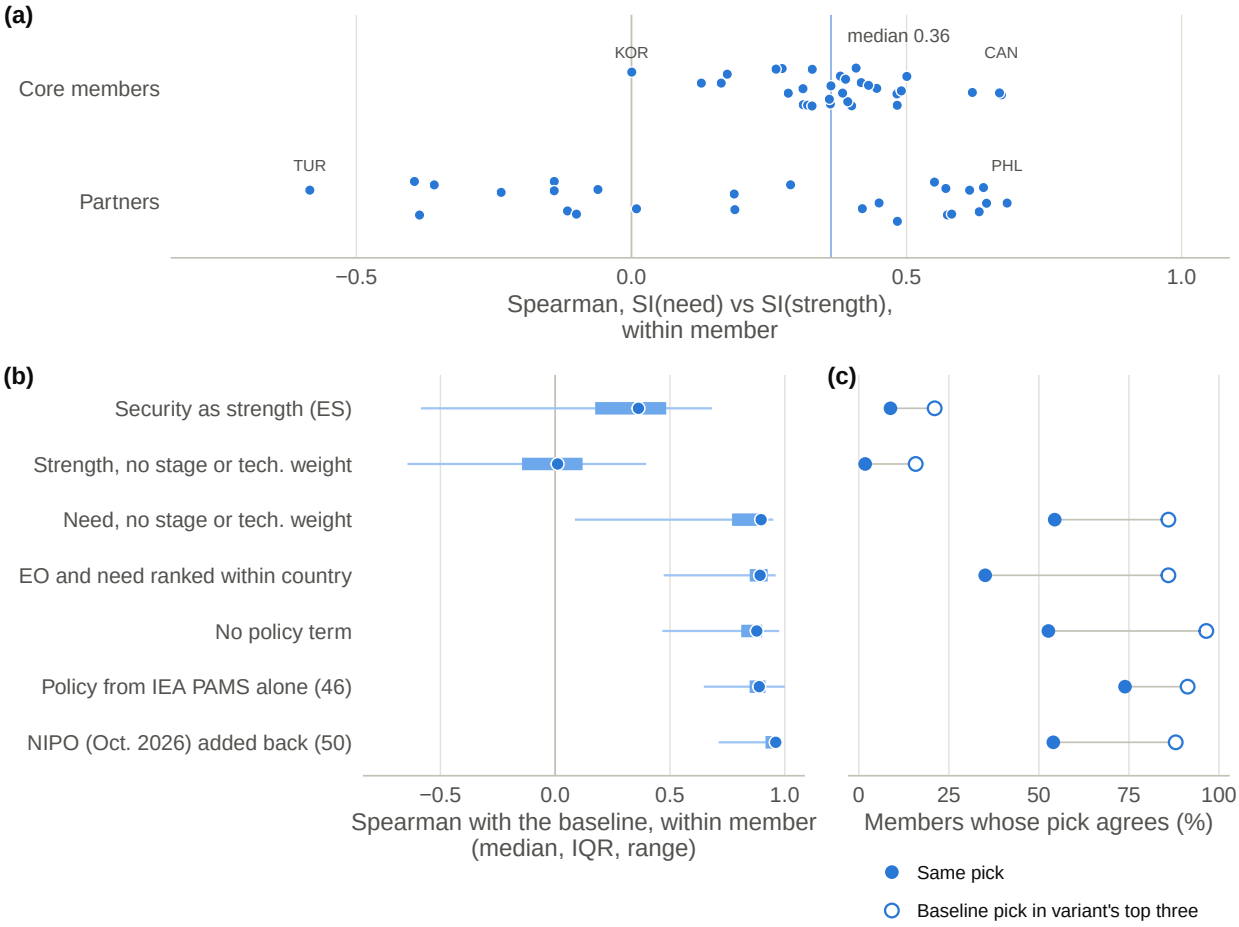

Figure 30: Sensitivity of the Strategic Index to its normative choices, coalition members. Panel (a): within-member Spearman correlation between the headline index (security as need, 1 − ES) and the index with security as strength (ES), all other terms unchanged; one point per member, by tier, median marked. Panel (b): within-member Spearman correlation of each variant with the headline (median, interquartile range and range): strength; strength without the stage and technology weights; need without those weights; opportunity and need ranked within the country; no policy term; policy from the IEA component alone (46 members scored on both); the October 2026 NIPO component added back (50 members with NIPO data). Panel (c): share of members whose pick is unchanged (filled) and whose headline pick is among the variant's top three (open); the IEA-alone and NIPO rows are shares of the 46 and 50 members whose index the variant changes, and over all 57 members 45 and 34 picks are unchanged (Table 22). All variants keep the endowment screen and the headline cells. Source: `index_outputs.rds`; the NIPO component of the October 2026 run.

Table 17: The bilateral pillars: units, direction, components and weights

	Friendshore (FS)	Partnership Opportunity (PO)	Development Potential (DP)
Unit	dyad (i, j, t, s)	dyad (i, j, t, s)	partner (j, t, s)
Reporter i	economy with a security need in (t, s)	exporter of (t, s)	none
Partner j	candidate for investment and sourcing	candidate export market	non-high-income economy
Components (weight)	τ^M_{ijts} imports from j (2); ν_{its} reporter need (2); e_{jts} partner EO rank (2); o_{ijts} outward investment in j (2); A_{ij} UNGA alignment (2); $1-\chi_{jt}$ Chinese-parent exposure (1; four Midstream cells); reporter EO rank (0)	τ^X_{ijts} exports to j (3); ε_{its} reporter EO rank (3); η_{jts} partner ES need (1)	eight partner components, weights $1, 1, 1, 1, 1.5, 1.5, 2, 1$ (Table 18)
Climate penalty	$0.10\,(1-g_t)(\mathrm{CPI}_i + \mathrm{CPI}_j)$	$0.05\,(1-g_t)\,\mathrm{CPI}_j$	none
Final transform	$\phi_\gamma[\cdot]_{ts}$ over dyads, after flooring at 0	$\phi_\gamma[\cdot]_{ts}$ over dyads, after flooring at 0	$\phi_\gamma[\cdot]_{ts}$ over partners
Summary to PSI	best five (t, s) per dyad; mean over the core reporters	best five (t, s) per dyad; mean over the core reporters	best five (t, s) per partner
PSI weight	0.4	0.4	0.2

Notes: Weights from `config/weights.yml`; within each pillar they are renormalized over the components observed (equation (59)). The FS penalty coefficient (0.10 per side) is fixed in code, the PO coefficient configured. g_t is the technology emission weight of equation (57), CPI the Climate Action Tracker rating. In Batteries, Electric Vehicles, Solar and Wind Midstream o_{ijts} is the CM-FDI project tie and χ_{jt} is defined; elsewhere o_{ij} is the IMF position and χ is absent.

is read as FS_{mets} and PO_{emts} (Section 11). $\phi_\gamma[x]_g$ is the S-curve of Section 4 within each cell of grouping g (ts: all dyads of a cell; its: reporter i's partners in the cell; i: all units of reporter i). Missing components are dropped and the weights renormalized,

$$\mathcal{A}_{\boldsymbol{w}}(x_1, \ldots, x_C) = \frac{\sum_c w_c\, x_c\, \mathbf{1}\{x_c \text{ observed}\}}{\sum_c w_c\, \mathbf{1}\{x_c \text{ observed}\}}, \tag{59}$$

so a missing component is never scored as zero.

Bilateral trade. Trade comes from the all-reporter Comtrade dyads for 2020 and 2024 (United Nations Statistics Division, 2026): the importer's own declaration where it reports the cell, otherwise the exporter's mirror declaration times the CIF/FOB factor 1.06; a reporter that declares no trade with a partner records a zero, and non-reporting economies enter only through their partners' declarations. With H_{ts} the HS6 basket of the cell (Section 3), the cell flow is

$$M^y_{ijts} = \sum_{h \in H_{ts}} m^y_{ijh}, \tag{60}$$

a product in several baskets counting in each. Among dyads that trade, the 2024 level L and the growth since 2020 G are ranked within the cell and combined 2:1, then re-ranked among the

reporter's own sources,

$$\tilde{\tau}^{M}_{ijts} = \mathcal{A}_{(2,1)}(\phi_\gamma[L]_{ts},\, \phi_\gamma[G]_{ts}), \qquad \tau^{M}_{ijts} = \phi_\gamma[\tilde{\tau}^{M}]_{its}, \tag{61}$$

so that τ^{M}_{ijts} measures j's place among i's sources. Recorded zeros form one tie block below every trading partner; a dyad with no observed 2024 flow takes the cell mean; the 15 cells without a basket carry no trade information. The export component τ^{X}_{ijts} is built the same way from i's exports.

Climate penalty. Each economy carries a Climate Action Tracker rating CPI_i (Climate Action Tracker, 2026) (0.25 to 1; EU members take the EU's, unrated economies the median, 0.75). The penalty is proportional to $(1 - g_t)\,\mathrm{CPI}$, with g_t the technology weight of equation (57). Because g_t is constant within a cell, it re-orders dyads within carbon-intensive technologies by the parties' climate ambition (Clausing and Wolfram, 2023) rather than lowering those technologies against clean ones.

10.2 The Friendshore index

Friendshore scores a friendshoring opportunity: a partner j in which i could invest and from which it could source to build trusted supply in (t, s). The score is high where i has a security need in the cell, j has an economic opportunity there, the two already trade and invest with each other, they are aligned, and j's foreign-invested plants are not mostly owned by Chinese parents. It indicates where investment and sourcing could go; it does not rank today's suppliers, which the import shares in the trade data show. Besides the import component it has the reporter's need, ranked among its own cells, and the partner's economic opportunity, ranked across countries,

$$\nu_{its} = 1 - \phi_\gamma[\mathrm{ES}]_i(i, t, s), \qquad e_{jts} = \phi_\gamma[\mathrm{EO}]_{ts}(j, t, s), \tag{62}$$

so that ν identifies which technologies i should friendshore, not which countries most need to. Because ν_{its} is the same for every partner of i in a cell, it sets how much the cell matters to i; the ranking of i's partners within the cell turns on j's opportunity, the trade and investment ties, alignment and ownership (and, through the penalty, j's climate policy). The dyadic alignment A_{ij} of equation (51) enters as it is, without ranking.

Outward investment. An outward position reveals an ownership or financing link that gives the investor a stake in the partner's capacity. Outside four cells, o_{ij} uses the reporter's outward direct-investment debt positions in the IMF Direct Investment Positions (International Monetary Fund, 2026a), averaged over 2020–2024 ($\bar{D}_{ij}$); positions involving 16 conduit financial centres, dominated by pass-through capital (Damgaard et al., 2024), are unobserved on both sides. With Y the 2023 GDP,

$$\tilde{o}_{ij} = \begin{cases} \mathcal{A}_{(1,1,1)}(\phi_\gamma[\bar{D}],\ \phi_\gamma[\bar{D}/Y_j],\ \phi_\gamma[(\bar{D}/Y_i)/Y_j]) & \text{if } \bar{D}_{ij} > 0, \\ 0 & \text{if } \bar{D}_{ij} \le 0, \end{cases} \qquad o_{ij} = \phi_\gamma[\tilde{o}]_i. \tag{63}$$

An absent record is missing, not zero. In Batteries, Electric Vehicles, Solar and Wind Midstream the tie o_{ijts} comes instead from the CM-FDI database of cross-border clean-technology manufacturing projects (Bandara and Net Zero Industrial Policy Lab, 2026): the projects of parents headquartered in i located in j, ranked on attributed counts and disclosed capital within the cell and then within the reporter.

Chinese-parent exposure. For partner j and technology t in the same four cells, χ_{jt} is the share of j's foreign-invested manufacturing owned by parents headquartered in China, Hong Kong or Macao: capital-weighted where capital is disclosed and by count otherwise, half of a joint venture attributed to the listed parent, defined only where j hosts at least two projects, and set to one for China, Hong Kong and Macao. It enters as $1 - \chi_{jt}$, so a partner whose foreign-invested capacity belongs to Chinese parents scores lower.

Composite and index. With the reporter's own EO rank carried at weight zero,

$$\tilde{F}_{ijts} = \mathcal{A}_{\boldsymbol{w}^{\mathrm{FS}}}\big(\tau^{M}_{ijts},\, \nu_{its},\, e_{jts},\, o_{ijts},\, A_{ij},\, 1-\chi_{jt}\big), \qquad \boldsymbol{w}^{\mathrm{FS}} = (2,2,2,2,2,1), \tag{64}$$

$$\pi^{\mathrm{FS}}_{ijt} = 0.10\,(1-g_t)\,(\mathrm{CPI}_i + \mathrm{CPI}_j), \tag{65}$$

$$\mathrm{FS}_{ijts} = \phi_\gamma\big[\max\big(0,\ \tilde{F} - \pi^{\mathrm{FS}}\big)\big]_{ts}. \tag{66}$$

The index rewards a match between the reporter's security need and the partner's economic opportunity, backed by existing trade and investment ties and political alignment.

10.3 The Partnership Opportunity index

A market is worth more to an exporter when the exporter is competitive in the technology, already sells there, and the market's insecurity signals demand for new supply. With the reporter's and the market's cross-country ranks,

$$\varepsilon_{its} = \phi_\gamma\big[\phi_\gamma[\mathrm{EO}]_{ts}(i,t,s)\big]_{ts}, \qquad \eta_{jts} = \phi_\gamma\big[1-\phi_\gamma[\mathrm{ES}]_{ts}(j,t,s)\big]_{ts}, \tag{67}$$

$$\tilde{P}_{ijts} = \mathcal{A}_{(3,3,1)}\big(\tau^{X}_{ijts},\, \varepsilon_{its},\, \eta_{jts}\big), \qquad \pi^{\mathrm{PO}}_{jt} = 0.05\,(1-g_t)\,\mathrm{CPI}_j, \qquad \mathrm{PO}_{ijts} = \phi_\gamma\big[\max\big(0,\ \tilde{P} - \pi^{\mathrm{PO}}\big)\big]_{ts}. \tag{68}$$

Unlike the Friendshore need term, η_{jts} compares the market's insecurity with that of other markets. The penalty falls on the market's climate policy only.

10.4 The Development Potential index

Development Potential describes partner j alone: its enabling environment, energy-security need, economic opportunity, the official development assistance it receives in each stage, and its energy use (Table 18). It is defined for the 132 partners that the World Bank does not classify as high

Table 18: Components of the Development Potential index

Component	Varies by	Construction	Weight
$d^{(1)}$ development index	j	S-curve across economies of the mean of the observed S-curved WDI series of a 40-series basket (2022–2024 averages; 13 inverted)	1
$d^{(2)}$ business environment	j	S-curve of the Doing Business score (2019, last release)	1
$d^{(3)}$ investment environment	j	S-curve of $(d^{(1)} + d^{(2)})/2$	1
$d^{(4)}$ energy-security need	j, t, s	$1 - \mathrm{ES}_{jts}$	1
$d^{(5)}$ economic opportunity	j, t, s	EO_{jts}	1.5
$d^{(6)}$ stage aid	j, s	S-curve of ODA disbursements to the stage's sector (OECD CRS)	1.5
$d^{(7)}$ stage aid intensity	j, s	the same per unit of 2023 GDP	2
$d^{(8)}$ energy use	j	S-curve of energy use per capita	1

Notes: Weights from `config/weights.yml` (`partnership_development_components`). Stage aid: industry to Midstream, energy to Downstream, mineral resources and mining net of coal and upstream oil and gas to Upstream. A partner without a record of a component has it dropped, not scored as zero. Sources and the WDI basket: Online Appendix OA.8.

income,

$$\widetilde{D}_{jts} = \mathcal{A}_{\boldsymbol{w}^{\mathrm{DP}}}\big(d^{(1)}_{jts}, \ldots, d^{(8)}_{jts}\big), \qquad \boldsymbol{w}^{\mathrm{DP}} = (1, 1, 1, 1, 1.5, 1.5, 2, 1), \qquad \mathrm{DP}_{jts} = \phi_\gamma\big[\widetilde{D}\big]_{ts}, \tag{69}$$

ranked across eligible partners within the cell. Only need, opportunity and stage aid vary across a partner's cells, so they decide which cells its best-five summary selects. Online Appendix OA.8 gives the 40-series WDI basket, the aid measure and the orientation choices.

10.5 From dyads to partners: best-five summaries and the PSI

The PSI collapses technology and stage before reporters. For a dyad, the summary of a pillar is the mean of its five highest cells,

$$T^{v}_{ij} = \frac{1}{K_{ij}} \sum_{k=1}^{K_{ij}} v_{ij(k)}, \qquad K_{ij} = \min(5,\, n_{ij}), \tag{70}$$

and T^{DP}_j is the same over the partner's own cells. Partnerships in energy technologies are sector-specific, and an average over all cells would penalize a partner that is strong in a few technologies; the summary is therefore optimistic by design. With R the set of reporters whose view is taken, the category scores and the index are

$$C^{k}_{j} = \frac{1}{|R^{k}_{j}|} \sum_{i \in R^{k}_{j}} T^{k}_{ij} \;\; (k = \mathrm{FS}, \mathrm{PO};\; R^{k}_{j} \subseteq R), \qquad C^{\mathrm{DP}}_{j} = T^{\mathrm{DP}}_{j}, \tag{71}$$

$$\mathrm{PSI}_j = \frac{\sum_{k \in K_j} w_k\, C^{k}_{j}}{\sum_{k \in K_j} w_k}, \qquad (w_{\mathrm{FS}}, w_{\mathrm{PO}}, w_{\mathrm{DP}}) = (0.4,\, 0.4,\, 0.2), \tag{72}$$

Table 19: Coverage of the bilateral partnership tables

	Friendshore	Opportunity	Development
Reporters	219	219	–
Partners	219	219	132
Reporter–partner pairs	47,742	47,742	–
Cells (i, j, t, s) or (j, t, s)	1,534,002	1,342,942	4,356
Technology–stage cells with an HS6 basket	18	18	–
Reporters with observed bilateral trade	208	–	–
Share of basket cells with observed trade	77.0%	77.5%	–
of which from the partner's mirror declaration	21.9%	21.8%	–
Reporters with IMF outward positions (other cells)	62	–	–
Share of cells with an investment component	18.1%	–	–
CM-FDI cells: share with a project tie	7.2%	–	–
CM-FDI cells: share with Chinese-parent exposure	12.4%	–	–
Share of cells with reporter need missing	12.5%	–	–
Partners with stage aid (Up/Mid/Down)	–	–	121/131/131
Partners in PSI_j (core view); pairs in PSI_{ij}	219 partners; 47,742 pairs		

Notes: Final rerun of 2026-10-12. Trade shares are over the dyad cells of the 18 technology–stage cells with an HS6 basket; observed trade is the importer's own declaration or, where the importer does not report, the exporter's mirror declaration times the CIF/FOB factor 1.06 (all-reporter Comtrade dyads, 2020 and 2024). The investment component is the IMF outward direct-investment position of the reporter in the partner (16 conduit financial centres excluded) except in the four cells (Batteries, Electric Vehicles, Solar and Wind Midstream) where it is the reporter's cross-border manufacturing projects in the partner recorded in CM-FDI. Development Potential covers the partners that are not high-income. Source: `partner_*_tbl.rds`, `partner_trade_coverage_tbl.rds`, `psi_tbl.rds`, `psi_dyad_tbl.rds`; `scripts/paper/fig_bilateral.R`.

where K_j is the set of categories observed for j (a high-income partner has no DP). The headline takes the viewpoint of the coalition's core: R is the 31 core members (Section 8), so that PSI_j is j's value to the economies that anchor the coalition; the full-coalition (57 reporters) and world views are alternatives. For one pair,

$$\mathrm{PSI}_{ij} = \mathcal{A}_{(0.4,0.4,0.2)}\big(T_{ij}^{\mathrm{FS}},\, T_{ij}^{\mathrm{PO}},\, T_{j}^{\mathrm{DP}}\big), \qquad i \neq j, \tag{73}$$

j's value to i. A partner is ranked only under the pillars' rankability rule: it is sovereign and at most half of its PSI weight rests on imputed or missing inputs. The PSI sees only direct links, although a replacement supplier may itself depend on the supplier it replaces (Freund et al., 2024; Carvalho et al., 2021), and it contains no prices or trade costs.

10.6 Results

Coverage and the trade matrix. Friendshore and Opportunity rate all 47,742 ordered pairs of the 219 economies, in 33 and 30 cells (Table 19). Over the 18 basket cells, 77.0 percent of the Friendshore trade components are observed (17.4 percent positive flows, 59.7 percent recorded zeros); mirror declarations supply 21.9 percent of the observed values, and without them 39.9 rather than 23.0 percent would be imputed. Dropping the mirror fill leaves the headline ranking almost unchanged (Spearman 0.997, the same top fifteen). IMF positions come from 62 reporters, 23 of

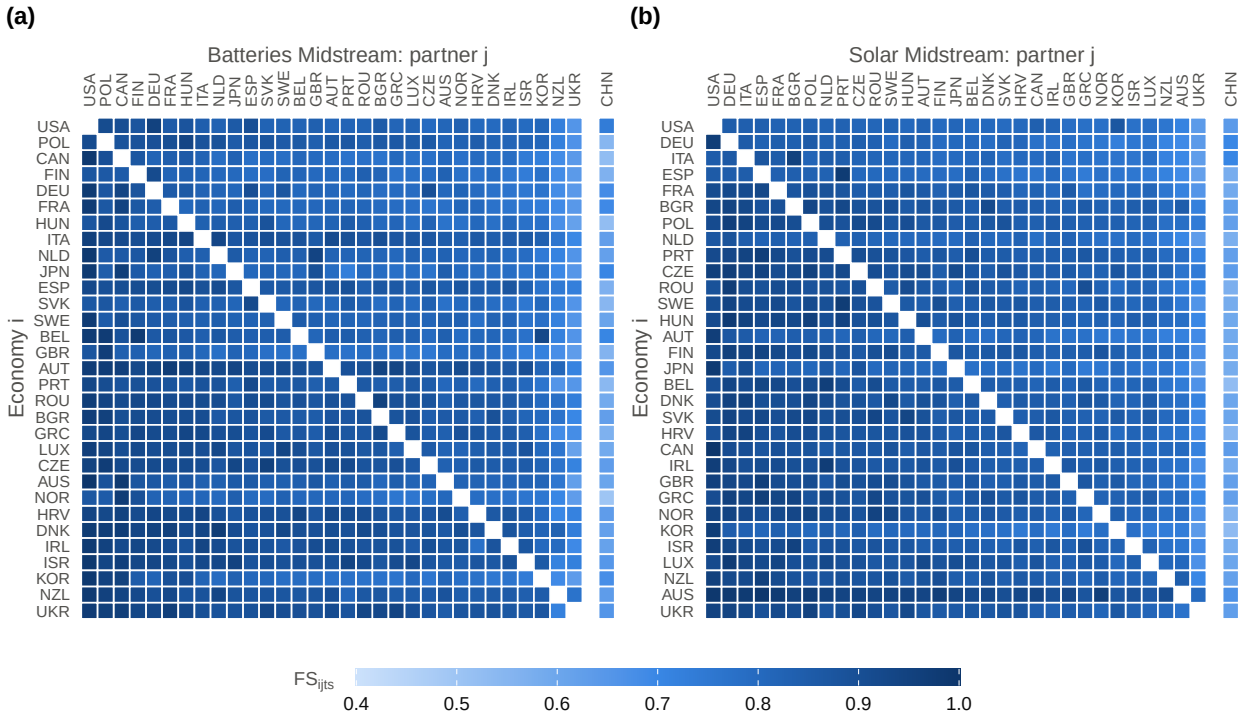

Figure 31: Friendshore index among the core members, (a) Batteries Midstream and (b) Solar Midstream. Rows are the economies i assessing friendshoring opportunities, columns partners j; colour is FS_{ijts} (equation (66)), the within-cell S-curve of the weighted mean of the components less the climate penalty. Rows and columns are the 31 core coalition members ordered by their mean rating as partners; the last column is China as a partner of each core member. The diagonal is empty. Every dyad shown has an observed import component (importer's declaration or mirror). Source: `partner_friendshore_tbl.rds`.

them core members, covering 9,171 pairs; with the conduit centres excluded, none of the ten largest outward counterparts of the United States or Japan is a financial centre. CM-FDI contributes 905 of its 1,042 projects, 234 investor–destination pairs from 29 investing economies. In the headline view 192 of the 219 partners are ranked: 24 are not sovereign, and Liechtenstein, Monaco and Kosovo exceed the imputed-share threshold (Online Appendix OA.8).

The coalition Friendshore matrix. Among the core members the partner's identity matters more than that of the economy assessing it (Figure 31; standard deviation of partners' mean ratings 0.052 and 0.051 in Batteries and Solar Midstream, of the assessing economies' 0.036 and 0.033), and the matrix is asymmetric by construction, since an economy that is secure in a cell and has a large opportunity there scores its partners low on need and is itself scored high on opportunity (Spearman of FS_{ijts} with FS_{jits} -0.40 and -0.41). China is rated 0.613 and 0.605 by the core, last of the 32 partners, although its trade and opportunity components are the highest; without alignment its rating would be 0.825 and 0.818.

What makes a leading friendshoring partner. The leading Friendshore partners of the United States (the United Kingdom, Germany, Canada) and of Japan (the United States, Portugal, Austria)

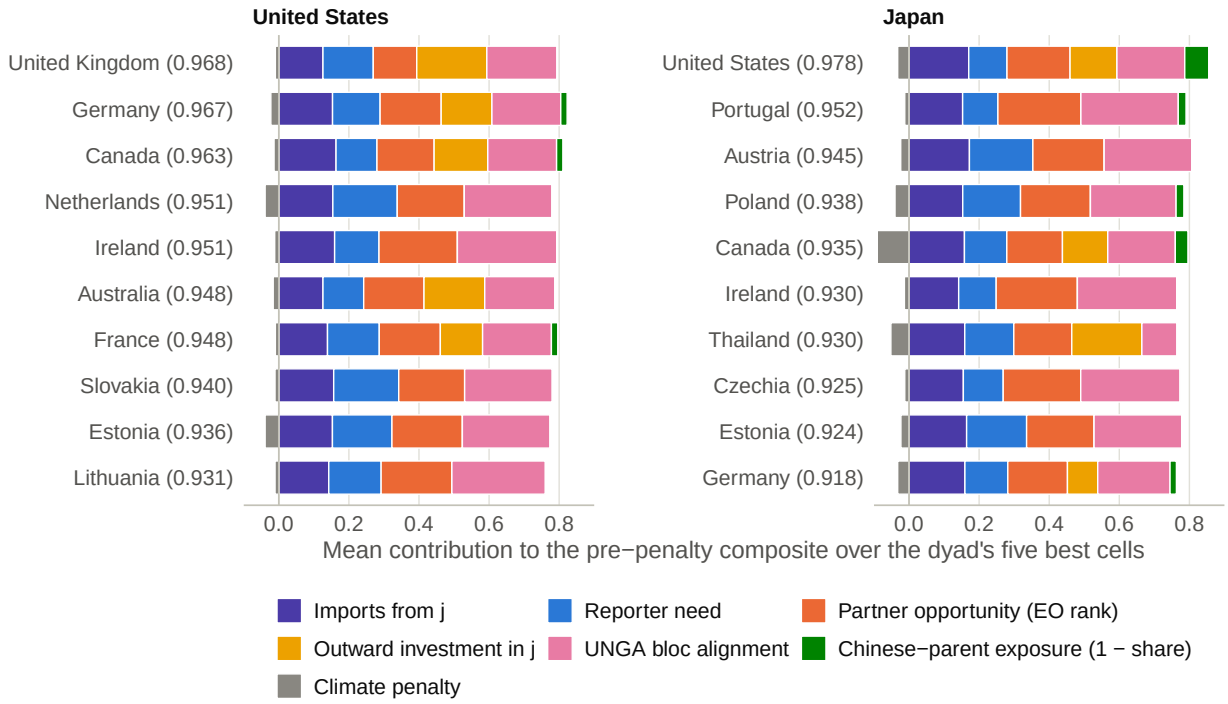

Figure 32: Composition of the Friendshore composite for the ten highest-ranked Friendshore partners of the United States (left) and Japan (right). Each bar is the mean, over the five technology–stage cells behind the dyad's best-five summary T_{ij}^{FS} (in parentheses), of the weighted component contributions $w_c x_c / \sum_{c' \text{ obs}} w_{c'}$, which sum to the pre-penalty composite; the climate penalty is the negative segment. Components and weights: imports from j (2), reporter need (2), partner opportunity (2), outward investment in j (2; IMF positions, or CM-FDI projects in Batteries, Electric Vehicles, Solar and Wind Midstream), UNGA bloc alignment (2) and Chinese-parent exposure scored as 1−share (1, defined only in those four cells); the zero-weight reporter EO term is omitted. A missing segment means the component is unobserved for that dyad and dropped from the mean. Partners are ranked among those that are sovereign and whose Friendshore dyad has an imputed weight share of at most 0.5 (158 for the United States, 170 for Japan). Source: `partner_friendshore_tbl.rds`, `partner_friendshore_top5_tbl.rds`; penalty recomputed from the technology emission index and the Climate Action Tracker ratings.

are all U.S.-leaning except Thailand, seventh for Japan (Figure 32). Alignment is the largest contribution to the top ten's composites (29.1 and 29.0 percent), followed by partner opportunity (23.0 and 24.9), imports (18.7 and 20.1) and need (18.7 and 16.9); investment contributes 9.9 and 6.9 percent. China ranks 70th among the Friendshore partners of the United States and 75th among those of Japan, and would rank 10th and 8th without alignment. Because absent investment records drop out rather than count as zero, and the summary keeps a dyad's five best cells, small aligned economies with a few strong cells rank high: Estonia and Lithuania are the ninth and tenth Friendshore partners of the United States, and neither they nor the Netherlands, Ireland (both conduit centres, whose positions are excluded) and Slovakia have an investment record in their five best cells. Scoring an absent record at the lowest rank instead replaces all five in the United States' top ten, with Spain, Japan, Poland, Korea and Belgium, but barely moves the headline index (Section 12.4).

The alignment component. Alignment carries weight 2 of 11 (18.2 percent) but 24.1 percent of the pre-penalty composite on average: for a core reporter it contributes 0.231 for a U.S.-leaning partner, 0.115 for a nonaligned one and zero for a China-leaning one. Setting its weight to zero changes the headline more than any other single choice examined: the Spearman correlation with the headline PSI_j is 0.869 (0.716 for C_j^{FS}), the median partner moves 17 places, and China would rise from 44th to 3rd, India from 39th to 16th, Indonesia from 62nd to 15th and Russia from 105th to 47th. The headline ranking is thus in large part a statement about political alignment with the United States; a purely economic reading of friendshoring opportunities should use the variant without it.

Chinese-parent exposure. Of the 905 CM-FDI projects, 406 have a parent headquartered in China, Hong Kong or Macao. The share is defined for 24 to 28 partners per covered cell, 47 economies in all, 31 of them coalition members (Figure 33); over the 94 partner–technology cells outside China its median is 0.50, highest in solar (median 0.75) and lowest in wind (0). Some partners on which the coalition relies are heavily exposed, among them Türkiye, Thailand, Malaysia and Viet Nam, and in the core Korea (batteries 0.91) and Hungary (electric vehicles 0.64). The component implements one channel, parent-company ownership, of the common-mode upgrade proposed in the working paper on the Allied Industrial Base (New Energy Industrial Strategy Center, 2026): plants in two supplier countries owned by the same parent do not diversify a buyer's supply. With modest weight and narrow coverage its effect on the headline is small (within-cell Spearman of FS with and without it 0.99; no PSI_j rank moves by more than four places) but concentrated where it should be: the change in core members' ratings correlates at -0.93 with the share, and China loses 0.085–0.095 per cell. The component also raises the ratings of partners whose few foreign-invested plants have non-Chinese parents, whoever those parents are: with it, the core's mean rating of Russia over its covered cell rises from 0.32 to 0.40, and Argentina's from 0.42 to 0.50 (Figure 33b). It measures the absence of Chinese ownership, not the presence of trusted ownership. It sees ownership of foreign-invested plants only, not dependence on Chinese equipment, precursors or licences.

The partner-level PSI. In the headline view (Figure 34) the United States (0.936), Germany (0.934), the Netherlands, the United Kingdom, France, Italy, Spain, Belgium, Poland and Czechia (0.904) rank highest. Core members hold 24 of the top 25 places (median rank 16); the first non-member is Slovenia (25th), a member of the EU node. Partners rank lower (median 64.5), from Saudi Arabia (38th) and India (39th) to Gabon (141st). China ranks 44th, a strong export market but a weak friendshoring opportunity in this view (21st on C_j^{PO}, 57th on C_j^{FS}), Taiwan 47th and Switzerland 51st. Opportunity varies little across partners (standard deviation 0.031, against 0.190 for C_j^{FS} and C_j^{DP}), so although nominally 40 percent of the index it accounts for 5.5 percent of the variance of PSI_j among the 130 partners with all three categories (Friendshore 63.8, Development 30.7 percent).

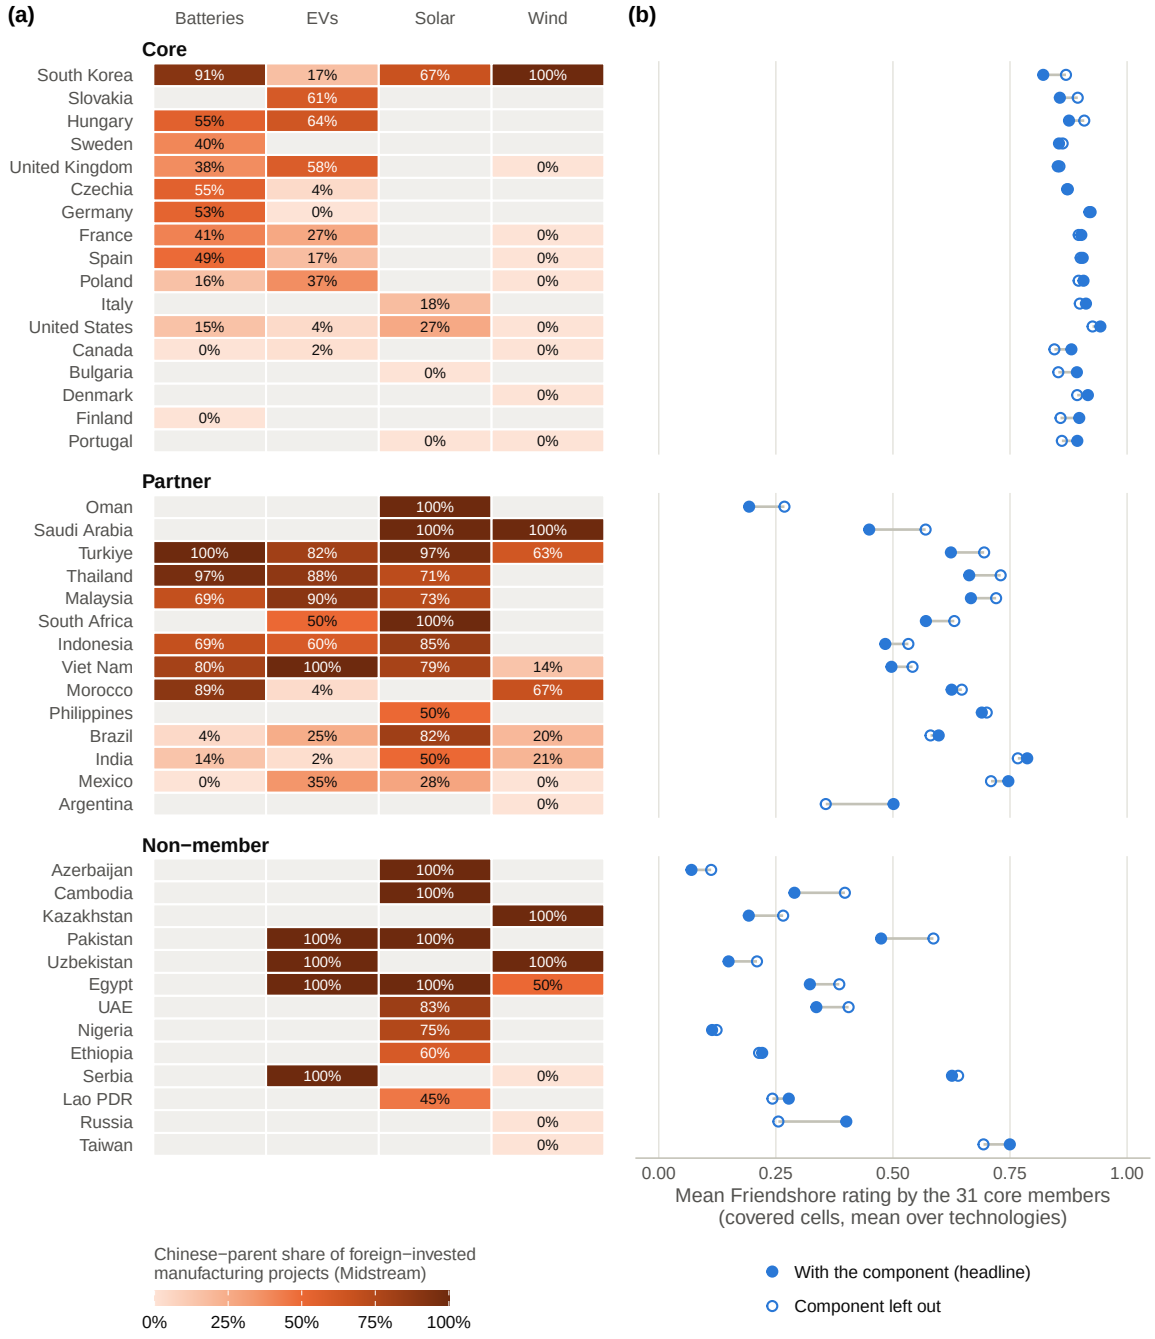

Figure 33: Chinese-parent ownership exposure of partners. Panel (a): for each economy hosting at least two foreign-invested manufacturing projects in a technology, the share of those projects owned by parents headquartered in China, Hong Kong or Macao (capital-weighted where capital is disclosed, by count otherwise; joint ventures attribute half to each parent), in the Midstream cells of batteries, electric vehicles, solar and wind; grey cells are undefined (fewer than two projects). Rows are grouped by coalition tier and ordered by the mean share; China, Hong Kong and Macao, set to one by construction, are omitted. Panel (b): the mean Friendshore rating of the economy by the 31 core members over its covered cells, with the component (filled) and with its weight set to zero and every later step re-run (open). Source: CM-FDI database, Net Zero Industrial Policy Lab, Johns Hopkins University (CC BY 4.0), 905 of 1,042 projects; `partner_cm_fdi_exposure_tbl.rds`, `partner_friendshore_tbl.rds`.

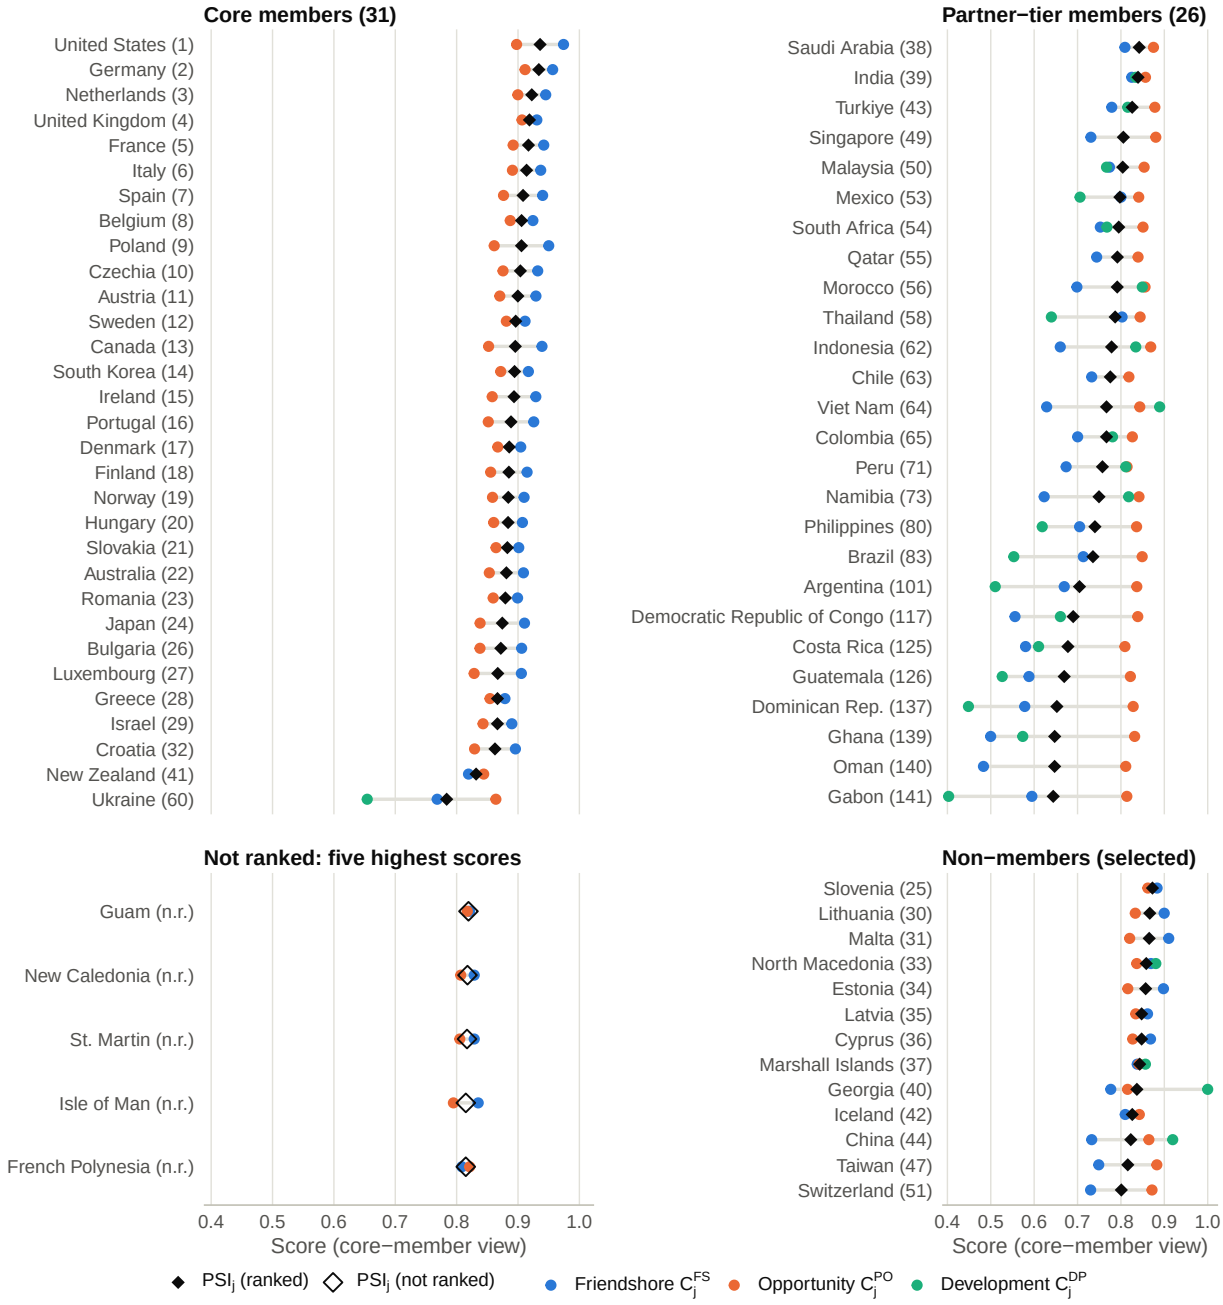

Figure 34: Partnership Strength Index in the headline view. Diamonds are PSI_j (equation (72)) with C_j^{FS} and C_j^{PO} averaged over the 31 core coalition members as reporters; dots are the three category scores, Friendshore C_j^{FS}, Partnership Opportunity C_j^{PO} and Development Potential C_j^{DP} (partners that are not high-income only). Panels: the 31 core members, the 26 partners, the ten highest-ranked non-members with China, Taiwan and Switzerland, and the five highest-scoring partners that are not ranked. Ranks in parentheses are among the 192 rankable partners (sovereign, imputed weight share at most 0.5); open diamonds and "n.r." mark partners without a rank. Source: `psi_tbl.rds`.

Table 20: The fifteen highest-ranked partners in the three views of the Partnership Strength Index

	Core members (31 reporters)		Full coalition (57)		World (218)	
Rank	Partner	PSI_j	Partner	PSI_j	Partner	PSI_j
1	United States	0.936	United States	0.893	China	0.813
2	Germany	0.934	Germany	0.879	India	0.787
3	Netherlands	0.922	France	0.868	France	0.783
4	United Kingdom	0.919	Netherlands	0.864	United States	0.782
5	France	0.917	Spain	0.861	Germany	0.780
6	Italy	0.914	United Kingdom	0.857	Indonesia	0.768
7	Spain	0.908	Italy	0.854	Netherlands	0.764
8	Belgium	0.906	South Korea	0.852	South Korea	0.761
9	Poland	0.906	China	0.850	Spain	0.760
10	Czechia	0.904	Belgium	0.848	United Kingdom	0.757
11	Austria	0.900	Canada	0.847	Italy	0.755
12	Sweden	0.896	Poland	0.840	Viet Nam	0.753
13	Canada	0.896	Czechia	0.838	Canada	0.750
14	South Korea	0.894	Austria	0.838	Austria	0.746
15	Ireland	0.893	India	0.836	Malaysia	0.746

Notes: PSI_j (equation (72)) with C_j^{FS} and C_j^{PO} averaged over the reporters of each view: the 31 core coalition members (the headline), the 57 core and partner-tier members, and every other reporter (218 per partner). Ranks among the rankable partners of each view (sovereign, imputed weight share at most 0.5): 192, 192 and 188 partners. Spearman correlations of PSI_j across the partners ranked in both views: core and full coalition 0.981 (192), core and world 0.881 (188), full coalition and world 0.948 (188). Source: `psi_tbl.rds`, `psi_full_coalition_tbl.rds`, `psi_world_tbl.rds`; `scripts/paper/fig_bilateral.R`.

Views of the index. The core and full-coalition views agree closely (Spearman 0.981 over 192 ranked partners, median rank change 5, 13 of the top fifteen in common); the core and world views (188 ranked) less so (0.881, median change 17, ten in common) (Table 20). The views differ in how they place the large nonaligned and China-leaning economies: China is 44th, 9th and first in the core, full-coalition and world views, India 39th, 15th and 2nd, Indonesia 62nd, 32nd and 6th. The partners whose rating depends on who is asking are those whose alignment differs from that of the core.

Friendshoring and market views of the same edge. For coalition pairs, an economy's Friendshore rating of a partner as a friendshoring opportunity and the partner's Opportunity rating of that economy as an export market agree to a degree (Figure 35; Spearman 0.715 over 95,312 matched cells), partly through the partner's EO, which enters both. Alignment, which enters only Friendshore, separates them: Friendshore exceeds Opportunity by 0.157 on average for same-bloc pairs and falls short by 0.24 for opposite blocs. The highest dyadic PSI_{ij} is Canada's rating of the United States (0.981).

Development potential. Among the 125 ranked partners, Georgia, Mongolia and Mauritius (1.00), Tuvalu and China (0.919) have the highest best-five summaries; the aid components, 35 percent of the nominal weight, provide 43.7 percent of the composite in their best cells. China's

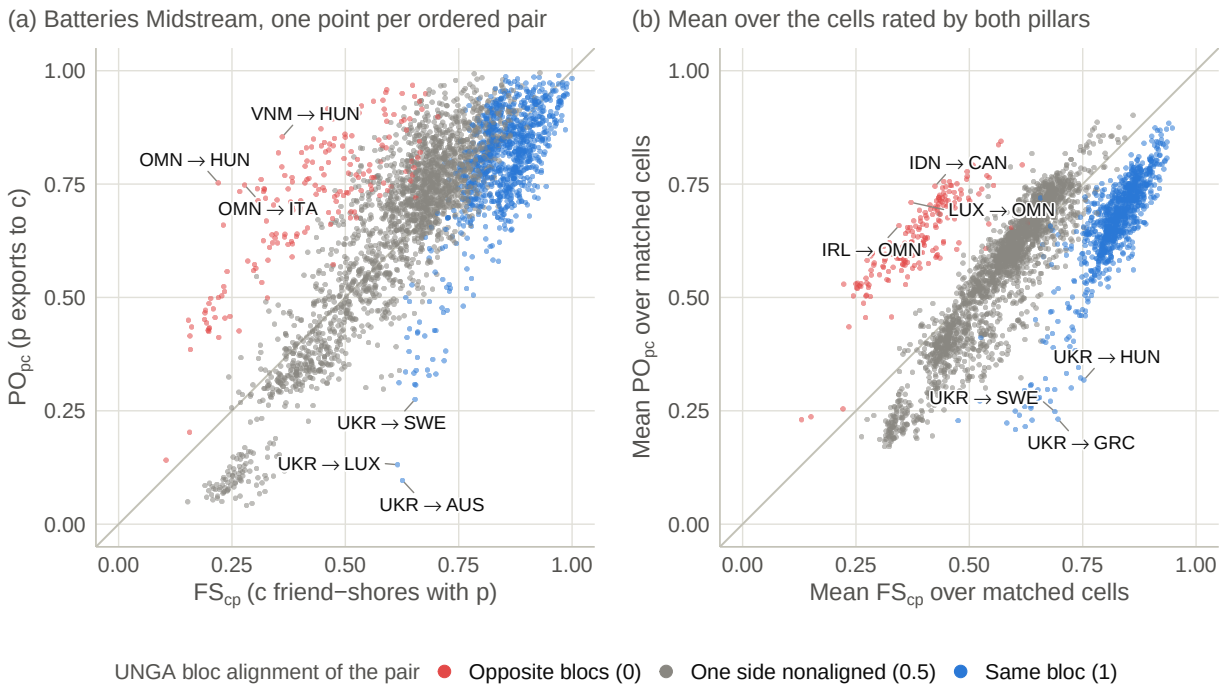

Figure 35: Friendshoring and market ratings of the same supply edge, coalition members. Horizontal: FS_{cp}, member c's Friendshore rating of member p as a friendshoring opportunity; vertical: PO_{pc}, p's Opportunity rating of c as a market. Panel (a): Batteries Midstream, one point per ordered pair of the 57 members (3,192 pairs). Panel (b): mean over the technology–stage cells rated by both pillars (28 to 30 per pair). Colour is the pair's dyadic UNGA alignment (1 same bloc, 0.5 when either is nonaligned, 0 opposite blocs); the line is the diagonal; the three pairs most favoured by each view are labelled. Source: `partner_friendshore_tbl.rds`, `partner_opportunity_tbl.rds`.

score is a reminder that the pillar rates absorptive capacity, not alignment.

11 The Allied Industrial Base: stress tests, partnerships and Sectoral Compacts

The indices of Sections 5–10 score countries, sectors and pairs one at a time. The case for an Allied Industrial Base turns on a different question (New Energy Industrial Strategy Center, 2026): what happens to the allies' supply when a dominant supplier is lost, how much of the loss their existing trade relationships can absorb, what coordinated trade adds, and where only new capacity closes the gap. A top-ranked country may add little if its strengths duplicate the coalition's, and a lower-ranked one may complete a chain, so the object is a country's contribution to the system rather than its rank.

This section treats the Allied Industrial Base as an *emergent network* of bilateral trade and investment relationships, and Sectoral Compacts as the institutions that coordinate groups of those relationships where joint action materially improves resilience. The analysis is a chain of explicit steps on the observed 2024 trade in U.S. dollars: a supply shock at each supply-chain node; the response of the existing relationships; the trade that optimized partnerships could achieve; the residual gap that trade cannot close; a standardised capacity increment at candidate hosts; the network of relationships that emerges; and the groups of nodes and countries for which a compact is worth forming, with a policy treatment for each node. Every step is reported, and no step is a weighted composite of the others: there is no AIB score. The analysis is conditional and positive. It shows what the observed network can and cannot do under a stated shock, not where production will locate, and it prices neither cost nor time to build. Appendix C states the programs and Online Appendix OA.9 traces four nodes through every step. The analysis replaces the allocation of production by a mixed-integer program with a calibrated diversification penalty that earlier drafts of this paper reported (Appendix D).

11.1 Nodes, flows and the two sets of economies

A node is a sub-sector of a technology stage in the HS6 master of Section 3: for example rare-earth compounds, permanent magnets or battery cells. Solar polysilicon and wafers, one sub-sector in the master, are split on their HS6 codes. The ten technologies with a trade basket (the nine headline technologies other than Geothermal and Green Hydrogen, plus Semiconductors) give 92 nodes in their Upstream and Midstream stages; Downstream deployment is left out. Where several technologies share the same HS6 set (permanent magnets, rare-earth compounds and rare-earth metals in Electric Vehicles and Wind, transformers in Electric Grid and Solar, pipelines in Oil and Gas) the cell is one physical node, counted once in network totals. The HS6 codes are the data, the node is the unit of optimization, the stage is the aggregation and policy frame, and every metric is recomputed from the flows summed to the node: no HS6-level score is averaged.

Flows are the reconciled 2024 Comtrade dyads of Section 3: the importer's declaration where the importer reports the node, otherwise the exporter's declaration times 1.06 (United Nations Statistics Division, 2026). An importer's demand for a node is its observed imports, so domestic production consumed at home lies outside the analysis and coverage is always coverage of *traded* demand. Observed exports are read as revealed tradable capability, not as spare physical capacity. Each node is checked against data-quality thresholds (world trade, the number of material exporters and importers, the share of mirror flows, codes shared with other nodes, HS revisions, and production far more concentrated than trade): 23 nodes are of high confidence, 68 usable with caution and one, cobalt ores and concentrates, too thin to optimize after thin nodes are merged into a sibling linked by a material flow (monazite into rare-earth compounds). Ninety-one nodes are optimized.

Two sets of economies are kept apart. The *demand scope* is the set of importers whose lost supply the analysis seeks to restore: the 57 coalition members of Section 8, 31 core members and 26 partners, each EU member in its own right. The *candidate partners* are the exporters that may open, expand or redirect relationships toward the scope: any economy other than the shocked one, with at least USD 1 million and 0.05 percent of the node's world exports (the larger bar binds); a median node has 43 candidates (9 to 74). The coalition is thus the set of economies protected, not a closed supplier set, and a supplier outside it counts wherever it supplies. Open ship registries (Liberia, the Marshall Islands, Panama and the Bahamas), which trade vessels under their flags, are in neither set. Compacts and network edges are formed only in the *electro-industrial* scope, the 70 nodes of Batteries, Electric Vehicles, Solar, Wind, Electric Grid, Semiconductors and Nuclear; coal, oil and gas nodes are modelled and reported but form no compact. Which economies are protected, which may supply them and which technologies are strategic are preferences, and Section 12.5 reports the results under other choices.

11.2 Shocks, existing relationships and optimized trade

Shocks. The headline shock removes China's exports in every node, with the re-exports of Hong Kong and Macao; sensitivities halve them or remove the largest supplier of the sub-sector, the stage or the technology. Two readings of a shock are kept. Under *hold*, the headline, the shocked economy keeps buying: the shock is an export restriction, so other exporters' sales to China stay with China, which competes for the same supply. Under *release*, a decoupling, China's purchases fall by the same fraction and the exports headed to it are freed for others. Release is the more optimistic reading wherever third countries sell much to the shocked economy, as Myanmar and Laos do in rare-earth concentrates and Chile in lithium. Shock exposure is the share of the scope's traded demand for the node that the shock removes.

Three states. In state A nothing adapts: the shocked supply disappears. In state B the surviving candidates may reallocate only through relationships observed in 2024, plus keeping their own exports at home, and an existing relationship may grow to at most twice its observed size. In state C, optimized partnerships, any candidate may serve any importer in the scope. A candidate's available

supply is its current shipments to the scope plus, in the *reallocation* scenario of the headline, its exports to markets outside the scope (under hold, not its sales to China); in the *conservative* scenario every surviving shipment into the scope stays where it is and only the supply the shock frees can move. What a candidate draws beyond its own shipments to the scope is reported as diversion, supply taken from buyers outside it. The bound on state B matters: without it, a relationship of USD 10,000 could carry any volume and existing relationships would be as flexible as new ones. The difference between the two states,

$$\text{coordination dividend}_n \;=\; C_n^{\mathrm{C}} - C_n^{\mathrm{B}}, \tag{74}$$

where C_n is the share of the scope's traded demand for node n served after the shock, is the value of new or expanded relationships, that is, of coordination. The residual gap $1 - C_n^{\mathrm{C}}$ is what trade cannot close.

The program. States B and C are linear programs over the flows from candidates to importers, solved lexicographically: each objective is optimized only among the solutions that keep the earlier ones within a tolerance of their optimum (Ehrgott, 2005; Makhorin, 2020). The objectives are (1) to maximise demand served; (1b) to cut surviving shipments as little as possible, so that trade the shock did not touch is not reshuffled; (2) to preserve revealed specialization, weighting exporters by capped revealed comparative advantage (Balassa, 1965) or by their production share where a proxy exists; (3) to favour relationships with higher Export Opportunity (PO of Section 10, exporter to market); and (4) to favour revealed policy and climate compatibility (similarity of IEA policy intensity in the node's technology and stage and of Climate Action Tracker ratings). The tolerance on coverage is 0.05 percent, so the later objectives decide only among allocations that serve the same demand. No geopolitical alignment score enters, and none of the scores is a weight on coverage. Appendix C gives the program.

Physical capability. Trade values are a poor guide to who can produce where the dominant producer consumes most of its own output: world trade in polysilicon and wafers is far below world production, and HS 3818.00, the wafer heading, is mostly semiconductor wafers from Japan, Taiwan and Korea. In the 11 nodes with production or capacity shares covering at least 80 percent of world output (IEA mining and refining shares, International Energy Agency, 2026a; manufacturing capacity, Rhodium Group and MIT Center for Energy and Environmental Policy Research, 2026) the headline is *production-constrained*: an exporter the physical data list as a producer keeps its full trade response, while one they do not list (a re-exporter, stocks or a different product under the same code) keeps its current shipments to the scope but cannot expand or redirect toward it. Shares are not multiplied into trade values, since production is a volume and trade a value. The *trade-only* result, in which exports alone bound supply, is kept beside it. Where the class of a node rests on low trade exposure while physical and trade concentration diverge by 25 points or more, it carries the warning PHYSICAL CAPABILITY NOT VALIDATED.

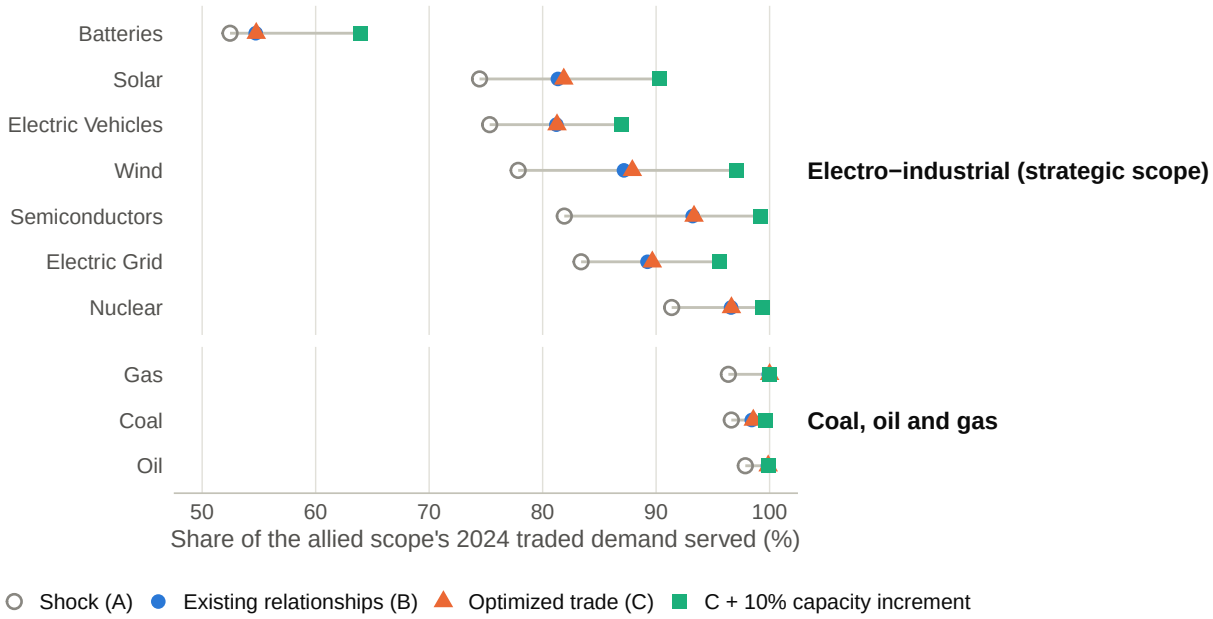

Figure 36: Coverage of the allied scope's traded demand after the shock, by technology. Each row is a technology: coverage of the 57 coalition economies' 2024 traded demand for its nodes when China's supply is removed (state A, open circle), with the response of existing relationships (B), with optimized trade partnerships (C), and with one synthetic increment of 10 percent of the node's demand at its leading host in every node with a residual gap of 5 percent or more (the investment step, a yardstick, not a forecast). Nodes shared by technologies count in each. Hold, production-constrained, reallocation. Source: `allied_trade_stress_test.csv`, `allied_investment_partnerships.csv`; `scripts/paper/fig_aib.R`.

11.3 Results: exposure, coverage and the coordination dividend

Removing China's supply costs the 57 economies 14.2 percent of their traded demand across the 91 nodes, USD 756 billion of USD 5,326 billion, and 22.9 percent in the electro-industrial scope (USD 702 billion of USD 3,063 billion), where coverage falls to 77.1 percent (Figure 36). Existing relationships restore it to 84.4 percent and optimized trade to 84.7 percent. Batteries are most exposed: 47.5 percent of the scope's traded demand is lost and 45.2 percent remains unserved after optimized trade. Solar (25.6 percent lost, gap 18.1), Electric Vehicles (24.7, 18.7), Wind (22.2, 12.1), Semiconductors (18.1, 6.7), Electric Grid (16.6, 10.3) and Nuclear (8.6, 3.4) follow; coal, gas and oil lose 2 to 4 percent and close almost all of it. The recovery is not new supply: under hold, all of it, USD 283 billion across the nodes and USD 232 billion in the electro-industrial scope, is supply drawn from buyers outside the scope, so the allies' coverage rises because others' falls.

The coordination dividend is close to zero. It is below one point in 81 of the 91 nodes, with a median of 0.05 points, and reaches the five-point threshold for coordination only in wind towers, at 6.7 points, where existing relationships already restore 93.3 percent (Figure 37). The reason is the reach of the existing network: with global candidate partners and existing relationships allowed to double, the network of 2024 already carries almost everything trade can do, and what remains is the difference between what the world outside China exports and what the allies lost. In the

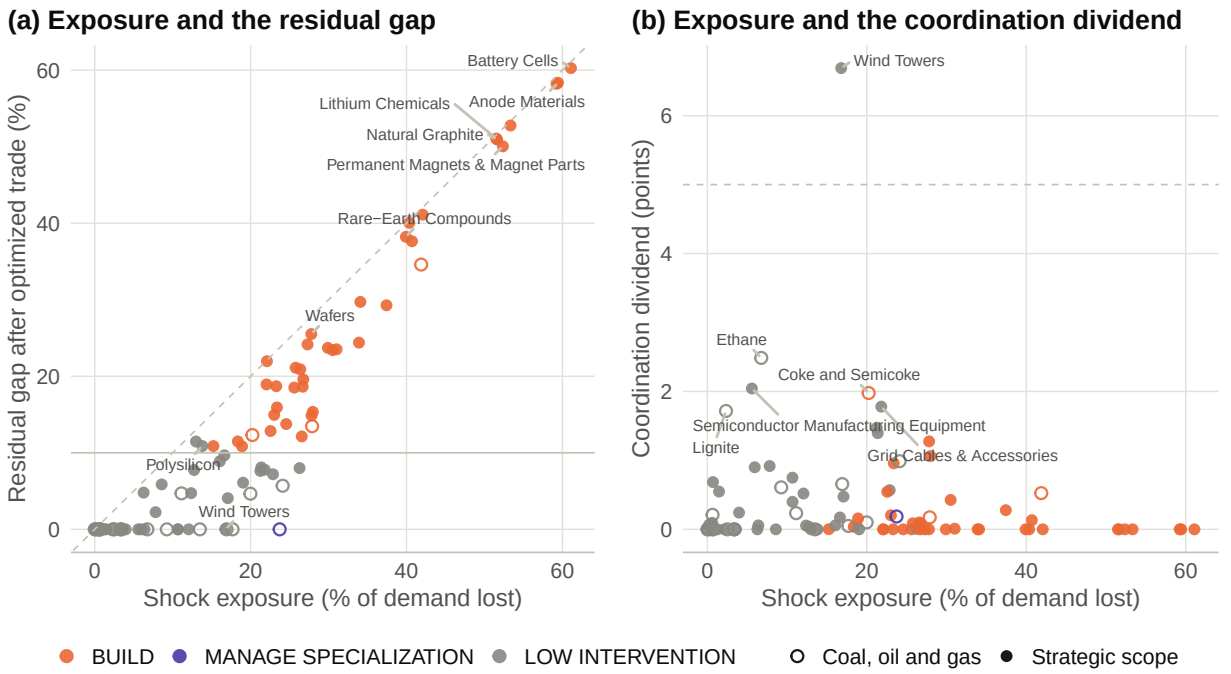

Figure 37: Shock exposure, the residual gap and the coordination dividend by node. Each point is one of the 91 optimized nodes, coloured by its class (Section 11.6); open points are coal, oil and gas nodes outside the strategic scope. Panel (a): the residual gap after optimized trade against exposure; on the dashed diagonal trade restores nothing, and the solid line is the 10 percent gap above which an exposed node is BUILD. Panel (b): the coordination dividend, optimized minus existing coverage, in points; the dashed line is the five-point threshold of COORDINATE. China removed, hold, production-constrained, reallocation. Source: `aib_node_classification.csv`; `scripts/paper/fig_aib.R`.

most exposed nodes the gap is close to the exposure itself (panel a): seven nodes lose more than half their traded supply and recover little of it, battery cells (61.1 percent lost, gap 60.3), anode materials, vehicle batteries and packs, solar modules, permanent magnets, natural graphite and lithium chemicals. The problem the stress test reveals is capacity, not the coordination of trade.

11.4 Residual gaps and marginal investment

Only after optimized trade, and only in nodes where at least 5 percent of demand remains unserved, does the analysis ask where new capacity would help. It is a marginal capacity simulation, not a project appraisal: a standardised increment of 5, 10 or 20 percent of the node's demand-scope demand is added at one eligible host at a time and state C re-solved, and the gain in coverage is recorded with the change in concentration. A host is eligible only with revealed capability at material scale: revealed comparative advantage of at least one on exports of at least USD 50 million or 1 percent of world trade in the node, a production share of at least 1 percent, a world export share of at least 0.5 percent, or that comparative advantage in a node joined to it by a material link. Hosts are ranked by (1) the gain in coverage with a 40 percent supplier-share limit in force, so that capacity at an already dominant supplier counts for little; (2) the fall in concentration; (3)

capability at scale, the larger of the host's world export and production shares; (4) Friendshore (Section 10) from the importers whose supply was lost; and (5) policy compatibility. Friendshore orders capable hosts and never admits an incapable one.

In the headline 49 electro-industrial nodes qualify, with 83 distinct eligible hosts and a median of 20 per node. At the 10 percent increment the leading host closes the median gap from 18.7 to 8.7 percent, and closes it fully in 10 nodes; its gain is the full increment in the median node, since one increment is smaller than most gaps. Most leading hosts qualify on comparative advantage (41 of 49), five on production shares. Twenty-nine economies lead at least one node: Czechia leads seven (among them power converters, grid control panels, electrical steel, wind foundations and turbines), Viet Nam five (solar racking, cabling, module inputs, array cables and integrated circuits), the Philippines three, and Denmark, Spain, Finland, Indonesia, Korea, Malaysia, Taiwan and the United States two each.

The investor–host pairs follow from the same simulation: with every other flow fixed, the new capacity at the leading host fills the unmet demand of the importers that lost supply, in descending order of the host's Export Opportunity toward them. Only the leading (first-ranked) host of each node enters the flows; the hosts ranked second to fifth are alternatives for the same increment and are never added to it. Each importer served is an *investor*: the buyer whose lost supply the new capacity replaces and which therefore has the interest to finance or contract for it. Across the 49 nodes the leading hosts' capacity supplies USD 178 billion to 57 investors in 618 investor–host pairs, beside USD 29 billion that hosts keep for their own demand (Figure 38). The largest pairs are Germany with Finland (USD 9.9 billion, in vehicle batteries and packs), the United States with Hungary (USD 7.4 billion, charging infrastructure), with the Philippines (USD 6.0 billion in three nodes) and with Taiwan (USD 5.8 billion, battery cells), and Mexico with Hungary (USD 5.7 billion). Core members host 58.9 percent of the supply, partners 33.6 percent and economies outside the coalition 7.4 percent, chiefly Taiwan. The supply-weighted mean Friendshore of the investor toward the host is 0.77.

11.5 The emergent network and country roles

The relationships the analysis selects form the emergent network: 2,029 directed pairs among 108 economies in the electro-industrial scope, oriented as goods move. Trade selections (a new or expanded relationship in the optimized allocation) give 1,704 pairs, and investment selections (the leading host serving an investor, turned round so that the host supplies the investor) 669; 344 pairs carry both. Each economy's roles are kept apart rather than ranked (Figure 39): 105 economies supply through trade, the 57 economies of the scope buy and invest, and 32 host a leading increment under one of the two simulated shocks. These counts include every positive role; the dashboard names a role only where it reaches at least one percentage point of node demand (the share of a node's demand the economy serves or receives under the headline shock, summed over nodes) and lists smaller roles as minor. Twenty-five economies hold all four roles. Economies outside the coalition provide 14.4 percent of the USD 159 billion of added trade, and the 44 that only supply

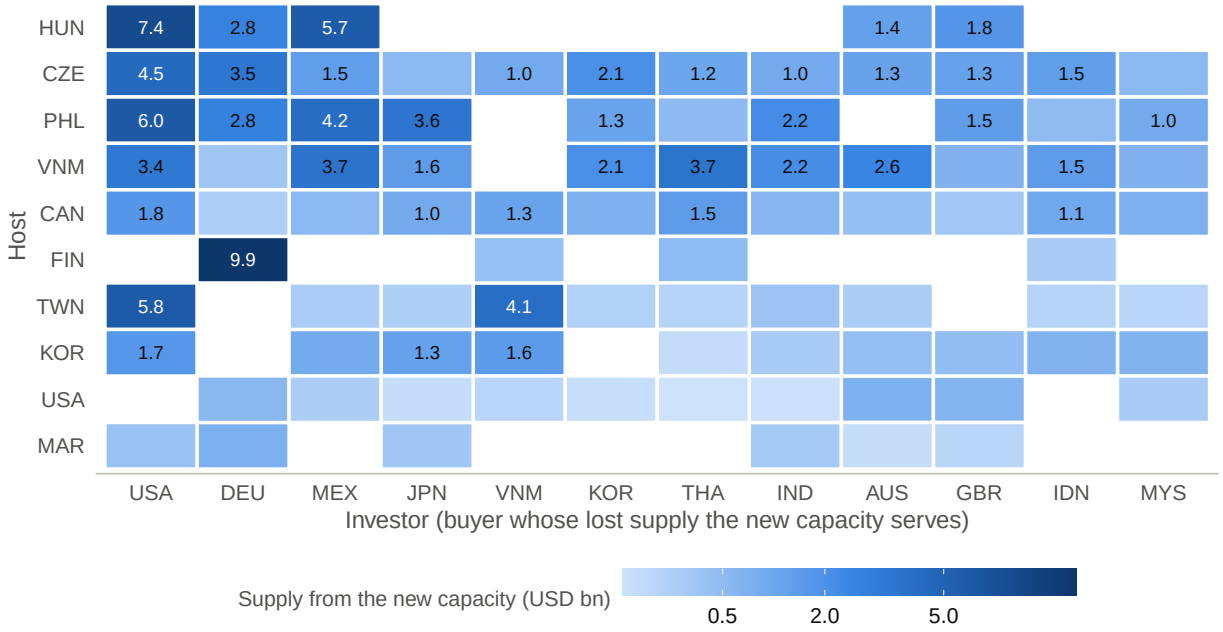

Figure 38: Investor–host flows of the investment step. Each cell is the supply, USD billion, that a 10 percent capacity increment at the leading host of a node would deliver to the investor, an importer in the demand scope whose lost supply it replaces, summed over the 49 electro-industrial nodes with a residual gap of at least 5 percent; values of at least USD 1 billion are printed. Rows are the ten largest hosts and columns the twelve largest investors, 73.1 percent of the USD 178 billion delivered to other economies; supply a host keeps for its own demand is excluded. China removed, hold, production-constrained, reallocation. Source: `allied_investment_pairs.csv`; `scripts/paper/fig_aib.R`.

are all outside it.

Added trade concentrates among a few suppliers: Korea adds USD 19.1 billion to 43 partners and Japan USD 16.7 billion to 55, followed by the United States (USD 11.2 billion), Germany (USD 10.5 billion), Italy and France. India, Singapore and the United States are the largest buyers of that trade, and the largest single pair is Korea to India (USD 12.0 billion over 20 sub-sectors). The hosts are a different group. The economies that would host the most new capacity, Hungary, Czechia, the Philippines and Viet Nam, with USD 26 to 29 billion each, are minor suppliers of added trade, while the largest investors, the United States (USD 32.2 billion across 25 nodes), Germany and Mexico, are also buyers. The roles answer different questions, which is why the network reports them separately and gives no single ranking.

11.6 Node classification

Each node receives one of four policy treatments, by rules applied in order to the headline results:

1. LOW INTERVENTION if the shock removes less than 15 percent of demand;
2. BUILD if the residual gap after optimized trade is 10 percent or more: new capacity is needed, with coordinated finance, guarantees and long-term offtake at the listed hosts;
3. MANAGE SPECIALIZATION if the node is resilient but its optimized supply is concentrated (the largest supplier holds 40 percent or more, the three largest 75 percent or more, or diversifying to a 40 percent limit costs five points or more): inventories, supply guarantees and reciprocal access with the dominant suppliers;
4. LOW INTERVENTION if existing relationships already restore 90 percent;
5. COORDINATE if the coordination dividend is five points or more: market access, rules of origin, procurement and offtake with the listed partners;
6. otherwise LOW INTERVENTION: existing trade is nearly sufficient.

Concentration is tested before adequate existing resilience because a node that copes through a few suppliers is a specialization to manage, not one to leave alone. A node can need several instruments, so the needs are also kept as labels (COORDINATE for a dividend of five points, BUILD for a gap of 10 percent, MANAGE SPECIALIZATION for the concentration test, each when exposure is at least 15 percent), and the continuous results stay beside the class.

Of the 92 nodes, 40 are BUILD, 50 LOW INTERVENTION, one MANAGE SPECIALIZATION (oil storage and transport equipment) and one has insufficient data; none is COORDINATE. In the electro-industrial scope 37 nodes are BUILD and 32 LOW INTERVENTION; the median BUILD node loses 27.8 percent of its traded supply and keeps a gap of 23.4 percent. Lithium chemicals and rare-earth metals need BUILD and MANAGE SPECIALIZATION together, and wind towers, LOW INTERVENTION because existing relationships restore 93 percent, keep COORDINATE as a need. Polysilicon and cobalt and nickel refining are LOW INTERVENTION on low trade exposure while China dominates their production, so both carry the physical-capability warning: their dependence arrives embodied

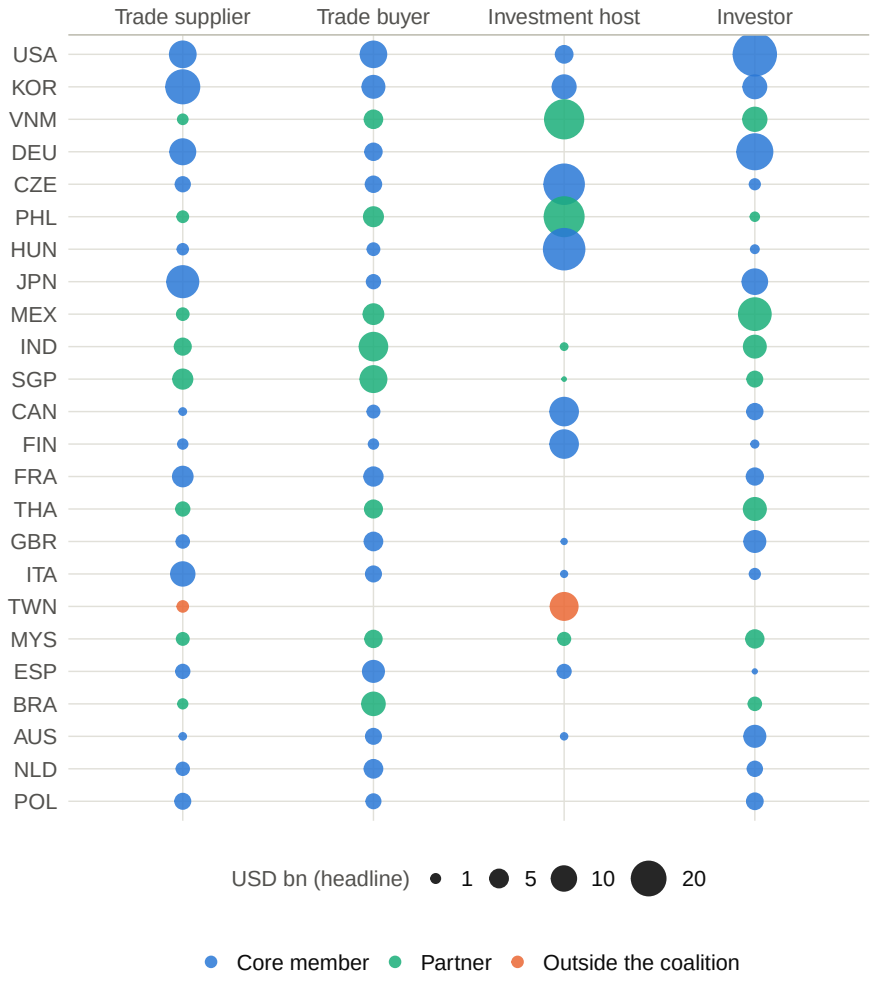

Figure 39: Country roles in the emergent network. Rows are the 24 economies with the largest volume across the four roles; dot area is the headline volume, USD billion: added trade supplied (trade supplier) and received (trade buyer) in the optimized allocation, and supply from the leading hosts' new capacity hosted (investment host) and received (investor), as in Figure 38. Colour gives the coalition tier. Electro-industrial scope, China removed, hold, production-constrained, reallocation. Source: `emergent_aib_country_summary.csv`, `allied_investment_pairs.csv`; `scripts/paper/fig_aib.R`.

in wafers, cells and battery materials. The classes are interpretations of the continuous results, made with stated thresholds; Section 12.5 shows how they move with the settings.

11.7 Sectoral Compacts

A Sectoral Compact is warranted only where a group of nodes and countries gains from acting together. The intervention nodes (BUILD, COORDINATE and MANAGE SPECIALIZATION) of the strategic scope are grouped by complete linkage, so that every pair of nodes in a compact passes three tests. *Chain coherence*: one node is upstream of the other within three links of a curated, directed physical and process chain (rare-earth oxide to metal and alloy to permanent magnet to motor or generator; lithium minerals to chemicals to cathode to cell to pack to vehicle; graphite to anode to cell; silicon metal to polysilicon to wafer to cell to module; copper and electrical steel to cables and transformers), or both feed the same downstream node directly; sharing a technology or a stage is not enough. *Partner overlap*: a cosine similarity of at least 0.35 between the nodes' recurring supplier vectors (optimized supply shares summed over every shock, with the leading hosts), or between one node's suppliers and the other's buyers. *Policy coherence*: a cosine similarity of at least 0.5 between the nodes' policy-need profiles (dividend, residual gap, excess concentration). A compact must also be one connected piece of the chain. A technology can therefore yield several compacts or none.

Exact minimum coalitions. A compact protects its *demand anchors*, the importers holding 60 percent of its lost supply (at most six). The anchors' coverage in a node when a set of countries coordinates is linear in membership: what reaches them with nobody coordinating, plus what each member adds by redirecting its available supply and, where it is a leading host of a node that needs capacity, one 10 percent increment. The *minimum coalition* is then the solution of a binary program: the fewest countries such that every node of the compact reaches 95 percent of the anchors' traded demand, with the anchors always members. Among coalitions of that size a second program picks the most robust, maximizing the smallest margin over the target across the compact's nodes, so that the coalition does not sit exactly on the target where losing any small supplier would tip a node below it; remaining ties go to the coalition adding the most supply (Appendix C). A greedy path, adding the economy that most reduces the shortfall, is kept for the view of coverage as countries join.

Tiers. The exact 95 percent coalition is the *core*. Within it, a *critical supply partner* is a member that is needed (without its supply the rest miss the target) and that no single other candidate can replace; in a minimum coalition every member is needed by construction, so substitutability is what distinguishes them. *Associate partners* are the fewest additions that reach 99 percent. A *critical external dependency* is a non-member whose loss would push a node below 95 percent with the coalition fixed and that supplies at least 1 percent of the anchors' demand. A group is a candidate compact only if its coalition lifts the anchors' coverage by at least five points over what their existing

relationships give them, and a coalition of fewer than three countries is a bilateral arrangement rather than a compact.

Results. The 37 intervention nodes of the scope form 22 candidate compacts, nine of them spanning several nodes (Figure 40 and Table 21). Every one is an Investment / Capacity compact, since every intervention node in the scope is BUILD, and all carry the same instruments: coordinated finance, guarantees, an investment pipeline, price support, demand aggregation and long-term offtake. Coalitions are small: three to nine countries, six in 13 of the 22. The exact coalition reaches 95 percent in all 22 and the robust tie-break is solved in all 22; the greedy path finds coalitions of the same size but with different members in nine. Twenty-nine economies belong to at least one coalition, led by Viet Nam (16 compacts), the United States (15), Japan (14), Germany (13), India and Korea (10 each). Critical supply partners appear in four compacts: Singapore and Taiwan in the battery compact (cells, foils, electrolyte, separators and packs), the United Kingdom in motors and magnets, Madagascar and Mozambique in anodes with natural graphite, and Viet Nam in rare-earth metals. Seven compacts have a critical external dependency, most of all motors and magnets, where seven non-members (Switzerland, France, Italy, Malaysia, the Philippines, Poland and Thailand) are critical; Thailand is also the one associate partner of any compact. Rare-earth compounds and metals sit apart from magnets because their partners and needs differ from their chain neighbours'.

The coordination dividend of a compact. Coordination within a coalition lifts the anchors' coverage by a median of 32.6 points (10.5 to 76.4) over their fragmented baseline, but that gain is almost entirely members redirecting their own exports toward each other. For all importers of the compact's nodes, the trade compact adds at most 0.04 points to what existing relationships achieve, in every compact: trade coordination moves supply among allies and away from others, and adds none to the system. What adds supply is the investment response, a median of 19.9 points of the nodes' demand, which brings 12 of the 22 compacts to 95 percent or more. The compacts are therefore best read as investment and offtake clubs for specific chains, with the coalition naming the members whose supply or capacity is indispensable and the external dependencies naming the risks that membership does not remove.

11.8 What the analysis does and does not show

The analysis measures what the 2024 trade network can do after a stated shock; it does not measure what production would cost, how long capacity takes to build or what governments are willing to pay. Demand is traded demand, so domestic production used at home is outside it. HS6 headings mix grades and uses: rare-earth compounds mix concentrates and separated oxides, and cables and converters serve many technologies; the data-quality flags say where. Shocks are applied node by node with no coupling across nodes, so a magnet shortage does not by itself reduce motor exports. Export Opportunity and Friendshore are technology-stage indices, not sub-sector ones. The physical

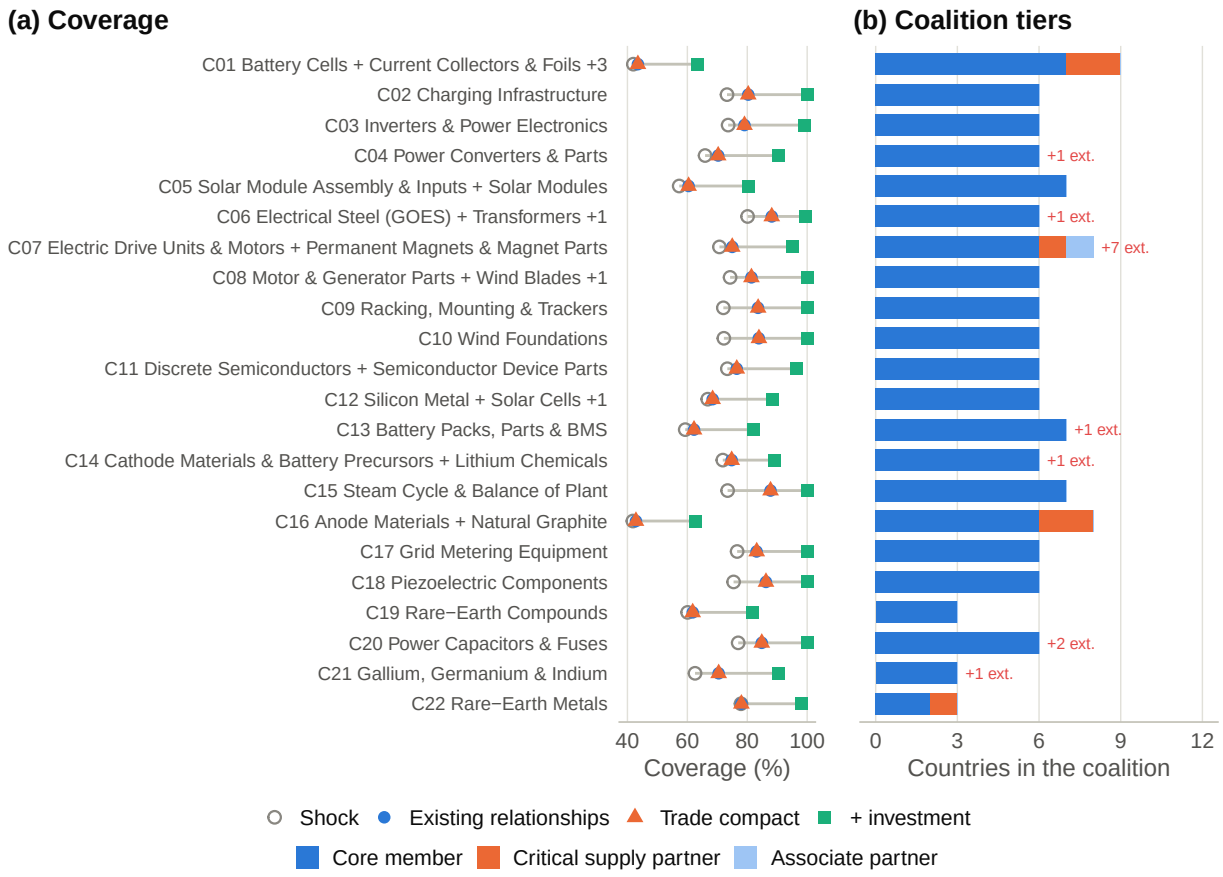

Figure 40: The 22 Sectoral Compacts. Panel (a): coverage of the allied demand for the compact's nodes after the shock, with existing relationships, with the trade compact (every economy keeps its existing response and the coalition's members may also open or expand relationships) and with one 10 percent increment at up to two member hosts per BUILD node. Panel (b): the coalition tiers, the exact 95 percent coalition split into critical supply partners and other core members, with associate partners added for 99 percent; "ext." counts critical external dependencies, which are not members. Compacts are ordered by the allied demand lost (Table 21). China removed, hold, production-constrained, reallocation. Source: `aib_compact_candidates.csv`; `scripts/paper/fig_aib.R`.

Table 21: The Sectoral Compacts of the headline run. Each row is a candidate compact: connected nodes of the electro-industrial chains that share partners and policy needs. Coalition: the exact minimum coalition at 95% of the demand anchors' traded demand in every node, critical supply partners (no single other economy can replace them) in bold; associates: the fewest additions reaching 99%; critical external: non-members whose loss pushes a node below 95% and that supply at least 1% of the anchors' demand. Coverage of the nodes' allied demand (%): shock / existing relationships / trade compact / trade compact plus one 10% increment at up to two member hosts per BUILD node. Lost: allied demand lost to the shock, USD bn. China removed, hold, production-constrained, reallocation. Source: `aib_compact_candidates.csv`; `scripts/paper/fig_aib.R`.

rule decides who can supply, not how much: a listed producer keeps its full trade response even where its production is small, and the 81 nodes without credible physical data, among them magnets, motors and most equipment, keep their trade-only result. The investment increment is synthetic and the same size everywhere, so the investment step ranks hosts and shows the order of magnitude of what capacity adds; it is not a project pipeline. Finally, the coordination dividend is near zero because the candidate universe is global and existing relationships may double; with a tighter bound on existing relationships coordination matters more, and Section 12.5 reports how far.

12 Robustness and validation

We vary one element of the construction at a time, holding the others at the final configuration, and ask how far the results depend on choices rather than data (Saisana et al., 2005; Nardo et al., 2008; Saltelli et al., 2008). For the pillars the comparison that matters is the ranking of countries within a technology–stage pair, so the main statistic is the within-pair Spearman correlation with the baseline, summarised across pairs and computed over the baseline's rankable cells: 4,163 of 6,232 scored cells in the 30 headline ES pairs and 4,301 of 7,131 in the 33 EO pairs. Every variant is recomputed from stored inputs with the pipeline's own builders, which reproduce the published indices at the baseline settings. Online Appendix OA.10 gives the details and further tables.

12.1 The pillars

Within-pair rankings are almost insensitive to the category weights and to the curvature of the S-curve (Figure 41). Over 1,000 Dirichlet draws centred on the configured weights (coefficient of variation 0.3 for a category of average weight), the median within-pair correlation is 0.997 in ES and 0.988 in EO, and equal weights give 1.000. Re-curving every component to $\gamma = 0.25$, 1 (the plain percent rank) or 2 gives medians between 0.964 and 0.997 in ES and between 0.965 and 0.992 in EO, the lowest at $\gamma = 2$. Much of this stability is mechanical: all scored countries of a pair observe the same categories, so a category that is constant within the pair shifts every country alike (equation (18)), and the median pair has only three varying categories in ES and four in EO. A high average can also hide wide rank bands for individual members (Online Appendix OA.10).

The imputation rule matters more. Without the global-average imputation ES is unchanged in the median pair (1.00) and EO nearly so (0.97), but the pooled EO correlation is 0.85 and the minimum 0.29; filling gaps with zeros lowers the EO median to 0.77. Outside the economies that the narrow sources cover, EO rankings depend on how gaps are filled, which is why the rankability rule withholds cells whose index rests mostly on imputed components. Its threshold is itself consequential: at $\tau = 0.3$ the Strategic Index shrinks from 3,154 cells for 174 countries to 1,577 cells for 107, and at $\tau = 0.7$ it grows to 5,156 cells for 194. The 2020 and 2025 vintages, which re-derive only the time-varying sources (about a third of the average cell's weight), give median within-pair correlations of 0.99 in ES and 0.87 in EO. Leaving out one category confirms that nominal weights and effective importance diverge (Paruolo et al., 2013; Becker et al., 2017): Technology Demand,

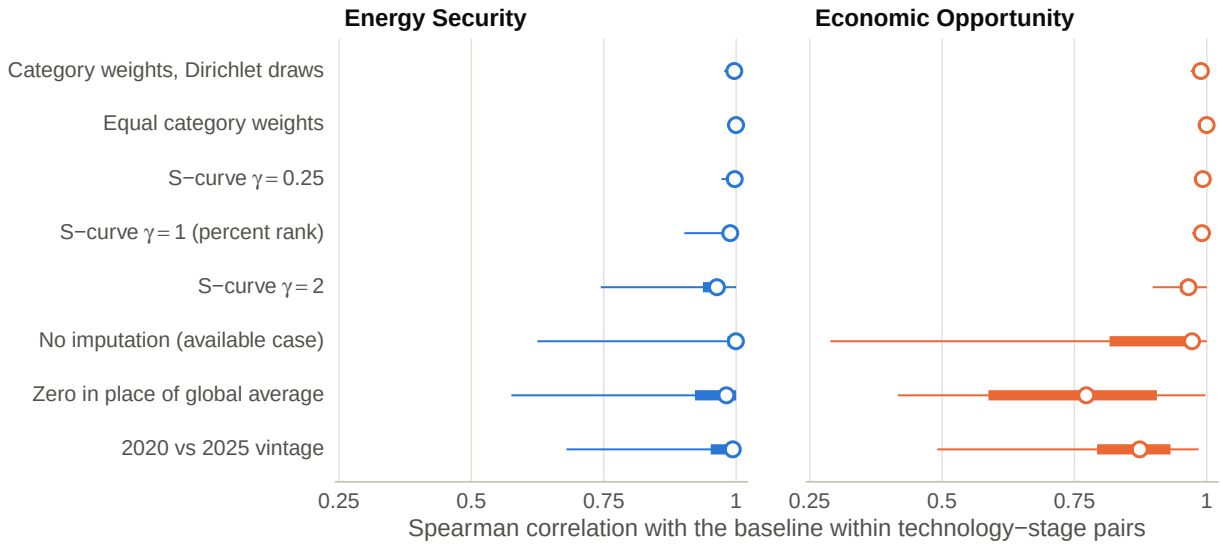

Figure 41: Stability of within-pair country rankings under alternative constructions of the pillars. Each row is one variant; for each technology–stage pair the Spearman rank correlation across countries between the baseline pillar and the variant is computed over the baseline's rankable cells, and the row summarises these correlations across pairs: open circle, median; thick bar, interquartile range; thin line, minimum to maximum. For the Dirichlet weight draws the per-pair value is the median over 1,000 draws. The S-curve rows rebuild both pillars from the theme tables with every component re-curved to $\gamma = 0.25$, 1 or 2 (baseline 0.5). "No imputation" removes every global-average rule, so uncovered countries drop the component; "Zero" fills them with 0. The last row compares the 2020 and 2025 vintages. Sample: 30 ES pairs (4,163 rankable cells) and 33 EO pairs (4,301). Source: `index_outputs.rds`, theme tables and vintages of the final run; `scripts/paper/fig_robustness.R`.

the largest nominal EO weight, barely moves the median ranking, while Foreign Dependency, Cost Competitiveness and Trade carry most of it.

12.2 The Strategic Index and the allied picks

The ordering of a country's sectors is robust; its single top sector is not. Under 1,000 Dirichlet draws of the five weights of equation (55), the median within-country Spearman correlation is 0.96 (0.88 to 0.99), but a member keeps its allied pick in 73 per cent of the draws on average, 16 of the 57 members in at least 90 per cent and 10 in fewer than half (Figure 42). Retention follows the pick's margin over the runner-up (Spearman correlation 0.84), and the margins are small: a median of 0.015, below 0.005 for 10 members and below 0.01 for 21, smallest for Luxembourg (0.0005) and Indonesia (0.0007). Electric Grid and Nuclear Midstream picks rest on the finest margins (medians 0.003 and 0.007, against 0.014 for Batteries Midstream). The Nuclear Midstream picks of Costa Rica, the Dominican Republic, Guatemala and Namibia have wide margins for a reason other than capability, and not because of a floor in the security pillar: each may pick among only four sectors, the Midstream stages of nuclear, oil, gas and coal (Namibia also Nuclear Upstream), Midstream nuclear security is compressed around its median, and the technology greenhouse-gas weight favours nuclear (0.999, against 0.42 for gas, 0.02 for coal and 0 for oil); without the sector

priors the Dominican Republic, Guatemala and Namibia move to Oil Midstream.

Table 22 reports discrete variants. Reading security as strength rather than need is the most consequential: the pooled Spearman correlation with the baseline is 0.33 and only 5 of the 57 picks survive. Without the sector priors 31 picks survive, with all terms ranked within country 20, without the policy term 30 and with equal weights 39. Switching the endowment screen off changes 41 picks, raising Upstream picks from 14 to 47: a country without uranium scores zero on the reserve and production terms, sits near the floor of the security pillar (86 of 174 countries share one ES value in Nuclear Upstream) and so shows a high need. The screen is a rule of eligibility, not part of the index, and without it the Upstream picks would largely reflect that floor. Tightening the screen to require recorded production, rather than any recorded reserves, removes all eight Nuclear Upstream picks, whose holders have small identified resources and no mine production, and the two Wind Upstream picks: nine members change pick and Gabon is left without an eligible sector. Two variants address the implicit sector priors of Section 9.2. Removing the cell-constant inputs from the pillar levels keeps the within-member ordering (median Spearman correlation 0.95) but only 29 of the 57 picks, and 23 picks then fall on Electric Grid Midstream; entering opportunity and need as within-pair ranks keeps 27 picks (median within-member correlation 0.80). The basis of the Policy index matters for its values more than for the picks: for the 65 countries with both components, the within-country correlation between policy on IEA PAMS alone and on the composite has a median of 0.48 (interquartile range 0.41 to 0.57), yet IEA PAMS alone keeps 45 picks, and requiring both components keeps the 46 CAT-rated members' picks exactly while removing the 11 scored on IEA PAMS alone. Adding back the October 2026 NIPO component (77 jurisdictions) keeps only 34 picks, shifting them from Batteries Midstream (27 to 15) towards Nuclear Upstream (8 to 14).

The picks also rest on the trade data. Setting the EIA-filled fossil production to zero changes no pick and removing the new Upstream trade baskets changes four, but dropping the Trade category keeps 29 of the 54 members that still have a pick, Trade on the Atlas basis 49, and the 2025 and 2020 vintages 48 and 44. The recorded history agrees: before the energy-trade file was completed, Electric Grid Midstream was the pick of 17 and Batteries Midstream of 11 of the 45 members then with a pick, against 4 and 27 of 57 in the final build. The allied pick is an informative but fragile summary, stable to the fill rules and basket additions of the final revision and sensitive to how trade is measured.

12.3 Vertical complementarities

The pillars score each stage separately, although shocks propagate along input–output links (Acemoglu et al., 2012; Carvalho et al., 2021) and capabilities in one activity ease entry into related ones (Hidalgo et al., 2007). A companion study tested whether a stage's EO should reward capability in the adjacent stage and its ES the security of its inputs. On the Atlas panel of 172 economies (1995–2023), with country–year and technology–year fixed effects, adjacent-stage capability is associated with a stage's market-share growth and entry into comparative advantage (Balassa, 1965) across countries, but the association is concentrated in fossil fuels and nuclear, close to zero for

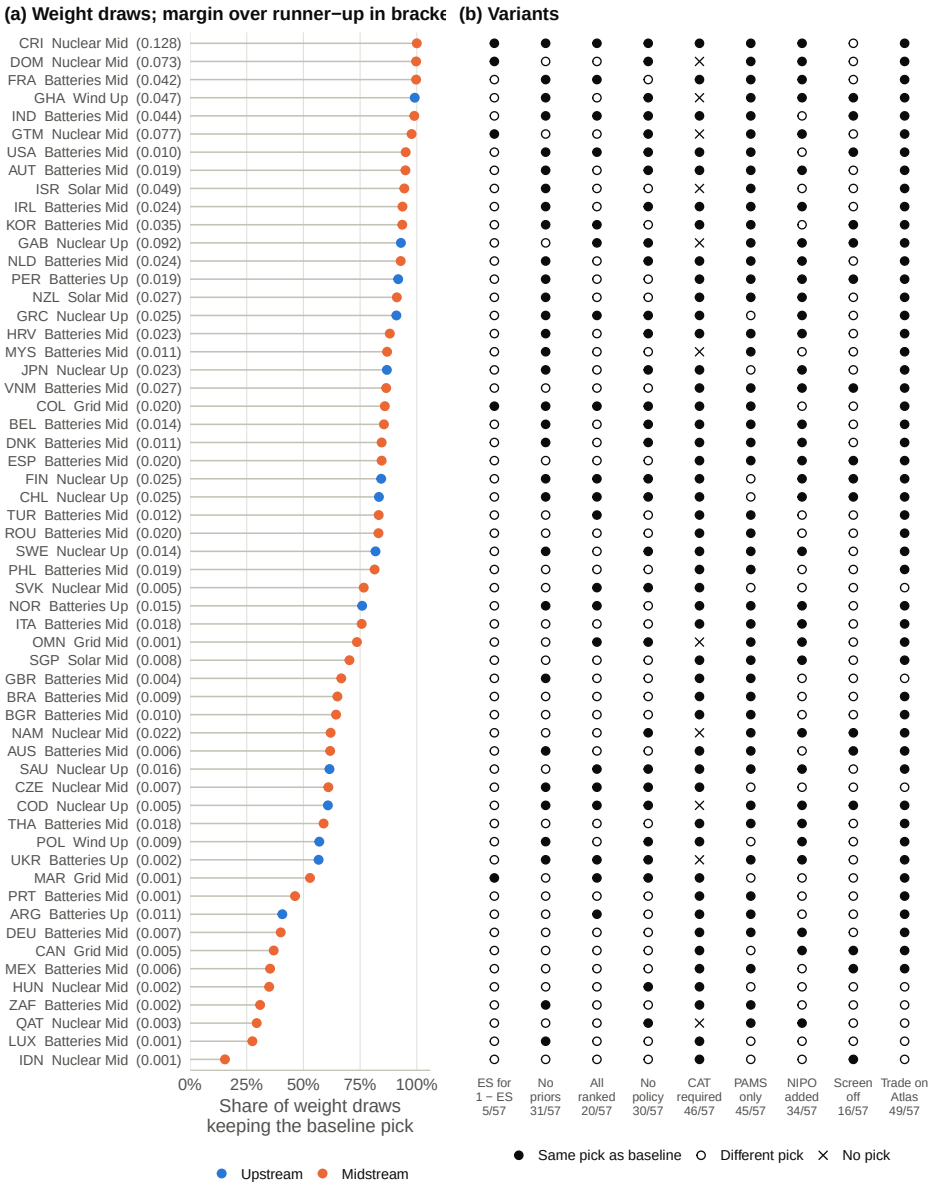

Figure 42: Robustness of the allied picks. Each row is a coalition member, its baseline pick (the eligible Upstream or Midstream sector with the highest Strategic Index) and, in brackets, the margin over its second eligible sector. Panel (a): share of 1,000 Dirichlet draws of the five Strategic Index weights, centred on $(0.2, 0.3, 0.3, 0.1, 0.1)$ with concentration 43.4, under which the pick is unchanged; colour gives the stage of the pick. Panel (b): filled circle, pick unchanged under the variant; open circle, changed; cross, no pick. Variants: security in place of need; no stage and technology priors; EO and 1 − ES S-curved within country; no policy term; both Policy components required; IEA PAMS only; the October 2026 NIPO component added back; the endowment screen off; Trade on the Atlas basis. Sample: 3,154 Strategic Index cells of 174 countries; 57 members, all with a baseline pick. Source: `index_outputs.rds`, `policy_component_tbl`, the October 2026 NIPO component; `scripts/paper/fig_robustness.R`.

Same pick as baseline	57	16	57	53	49	29	50	48	44

Notes: Number of coalition members whose allied pick, the Upstream or Midstream sector (excluding Geothermal and Green Hydrogen, and Upstream cells without a recorded resource base) with the highest Strategic Index, falls in each sector. All 57 members have a pick in the baseline. Panel A: ES for 1 − ES, security in place of need; No priors, without the stage and technology terms; All ranked, EO and 1 − ES S-curved within country; No policy, without the policy term; Equal weights, 0.2 on each term; CAT required, both Policy components required (`OPSI_POLICY_REQUIRE_ALL=1`), which leaves 65 countries with a Policy index and 46 members with a pick; PAMS only, CAT dropped for every country; NIPO added, the October 2026 NIPO component (GTA NIPO as of 5 October 2026) re-enters the Policy index with weight 4 (IEA PAMS 3, CAT 2), IEA PAMS still required, for its 77 policy-eligible jurisdictions. Panel B: Screen off, every Upstream cell eligible, including the 669 of 998 scored Upstream cells without recorded reserves or production; Zero for EIA, the oil, gas and coal production that the Energy Institute does not report set to zero instead of the EIA value (the rule until 11 October 2026); No new baskets, the Trade category removed from Electric Vehicles, Wind, Nuclear and Solar Upstream, whose trade baskets were added on 11 October 2026; Trade on Atlas, the Trade category of both pillars replaced by its Atlas-based counterpart of the 2025 vintage; No Trade, No Reserves, the category dropped from the pillars that score it and the remaining categories renormalised; 2025 and 2020 vintage, both pillars taken from the vintage builds, in which only the time-varying sources differ. The Policy index is the headline one in Panel B. Source: `index_outputs.rds`, `data/processed/vintages`; `scripts/paper/fig_robustness.R`.

the clean-technology chains, zero within country–technology cells, and of no help out of sample. A sourcing-weighted input-security measure reflects mostly alignment, its post-2022 shift is driven by Russia, and it did not predict the import shortfalls of 2021–22, whereas the concentration of sourcing did. At the weights the evidence supports, an adjacent-stage EO term moves one pick and an input-security ES term moves ten, no more than a placebo with permuted scores (Online Appendix OA.10). We therefore keep the stages uncoupled and leave to future work plant-level co-location from the CM-FDI and BNEF project data, input shares weighted by input–output coefficients, a test of sourcing concentration on the 2023 export controls on graphite and gallium, and a coupling of supply across the AIB nodes of one chain (Section 11.8).

12.4 The partnership index

The headline PSI averages the dyadic index over the 31 core members' viewpoints. The full-coalition view (57 reporters) gives nearly the same ranking (Spearman correlation 0.98 over 192 partners, 13 of the top 15 in common), although China moves from 44th to 9th; the world view (218 reporters) differs more (0.88, 10 of the top 15, median absolute rank change 17). The viewpoint is a choice of whose interests the index represents (Figure 43). Without the CM-FDI parts of friendshore, in the integration study on the inputs of 11 October 2026, the core PSI is practically unchanged (Spearman correlation 0.9998, largest rank change five places, same top 15).

Two further sensitivities concern Friendshore. Scoring an absent outward-investment record at the lowest rank rather than dropping it from the available-case mean leaves the core PSI almost unchanged (Spearman correlation 0.994, 14 of the top 15 in common, largest rank change 34 places, China from 44th to 37th), although it reorders the leading Friendshore partners of individual reporters (Section 10). The discretisation of alignment matters more. With continuous alignment, $p_i = s_i$ so that $A_{ij} = s_i s_j + (1 - s_i)(1 - s_j)$, the Spearman correlation with the headline is 0.904, 12 of the top 15 are shared, the median partner moves 13.5 places and China rises from 44th to 9th; with tercile blocs (cuts at $s = 0.164$ and 0.305, 65 economies in each outer bloc) the correlation is 0.952, 14 of the top 15 are shared and China ranks 40th. The quartile cuts thus hold China down mainly through the step from a continuous to a three-valued alignment, less through where the cuts fall.

12.5 The Allied Industrial Base

Every variant of the AIB analysis is computed in the same run as the headline, so the comparison holds the data fixed and changes one setting at a time. Figure 44 counts the node classes of the 70 electro-industrial nodes under each variant and Table 23 gives the residual gap by technology.

Hold versus release. Reading the shock as a decoupling rather than an export restriction is the setting that matters most. Under release, China's purchases fall with its sales and the supply headed to it is freed, so gaps shrink in every technology (Batteries from 45.2 to 39.4 percent, Solar from 18.1 to 11.1, Semiconductors from 6.7 to zero) and the BUILD nodes fall from 37 to 24. Twelve

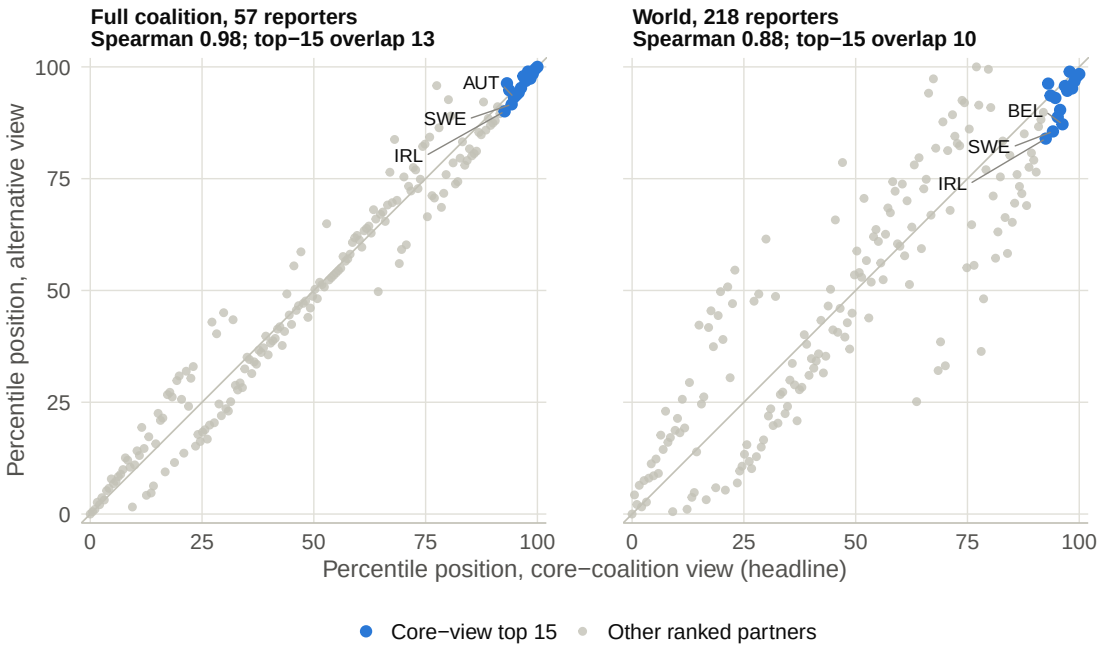

Figure 43: The partnership index from three viewpoints. Each point is a partner ranked in both views ($\tau = 0.5$), placed by its percentile position in the core-coalition view, the headline average over the 31 core members' ratings (horizontal), and in an alternative view (vertical): left, the full coalition of 57 reporters; right, the world of 218 reporters. Blue marks the top 15 of the core view; the labelled points are the three of them with the lowest position in the alternative view. Panel titles give the Spearman correlation with the core view and the overlap of the top 15. Source: `psi_tbl.rds`, `psi_full_coalition_tbl.rds`, `psi_world_tbl.rds`; `scripts/paper/fig_robustness.R`.

nodes turn to LOW INTERVENTION, among them cathode materials, current collectors and foils, separators, inverters, solar module inputs, wind substations and four semiconductor nodes; lithium chemicals becomes MANAGE SPECIALIZATION, because Chile's sales to China, freed, make it the dominant supplier. Hold is the headline because an export restriction is the shock the allies cannot choose, and release is the more optimistic reading wherever third countries supply China.

Production-constrained versus trade-only. The physical rule changes one class: wafers are BUILD with GCIM solar-wafer capacity deciding who can supply and LOW INTERVENTION on trade alone, where semiconductor wafers from Japan, Taiwan and Korea appear to replace Chinese solar wafers; the trade-only class carries the physical-capability warning, as do polysilicon and cobalt and nickel refining in both modes. Technology gaps differ by less than one point. The compacts under the two modes number 22 each, and 21 have the same nodes.

The growth bound. The coordination dividend depends on how far existing relationships may grow, and COORDINATE with it. Allowing them to grow by a quarter instead of doubling, two nodes reach the five-point threshold (wind towers at 8.6 points); at four times their size none does, and unbounded the largest dividend is 0.5 points. No class changes at any bound (Figure 44): in the headline the dividend is below the threshold wherever it is not already masked by adequate existing coverage. The absence of COORDINATE nodes is therefore not an artefact of the bound.

Supply scenario and shock size. In the conservative scenario every surviving shipment into the scope stays where it is and, under hold, nothing is freed, so the gap equals the exposure in every technology and 47 nodes are BUILD, ten more than the headline (grid cables and control panels, integrated circuits, nacelles and wind towers among them). Halving China's supply leaves 13 BUILD nodes, and the Batteries gap is still 21.5 percent. Removing the largest supplier of each sub-sector or stage instead of China produces the only COORDINATE classes of any variant: circuit breakers, nickel ores and reactor components under the sub-sector shock, copper refining and reactor components under the stage shock. Where the lost supplier is not China, the rest of the world can replace it, and new relationships do the replacing.

Global scope. Protecting every importer's demand, with every economy a candidate, removes the buyers outside the scope from whom the headline draws supply. Under hold nothing can then be recovered by trade: in every technology the gap equals the exposure (Table 23), BUILD rises to 48 nodes, and 30 compacts form. Under release 37 nodes are BUILD. The headline's recovery through trade is thus diversion from economies outside the coalition, as Section 11.3 reports, and the global run is the right benchmark for what the world as a whole can absorb.

Diversification and N-1. A supplier-share limit costs little coverage against the China shock: the tightest limit within two points of the unconstrained optimum is 25 percent in 77 of the 91 nodes. It buys no resilience to a second loss, however. With the largest remaining supplier removed

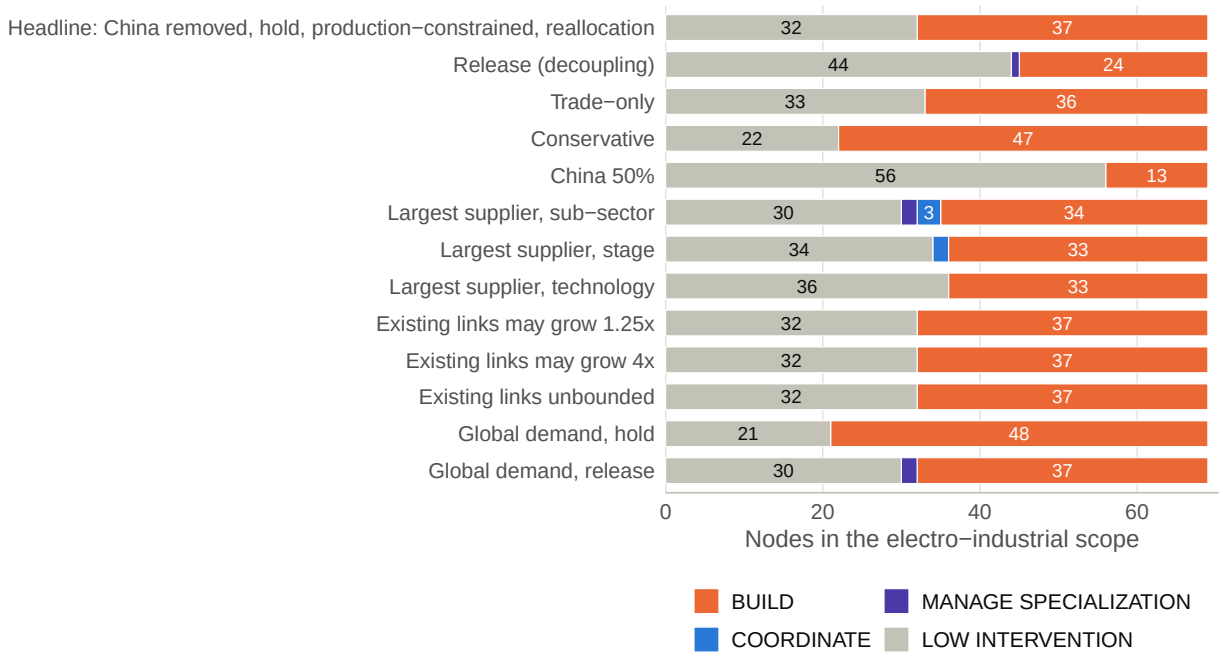

Figure 44: Node classes under each variant of the AIB analysis. Each bar counts the 70 nodes of the electro-industrial scope by class (one node, cobalt ores, has insufficient data in every variant and is not drawn). One setting changes at a time from the headline: the release reading of the shock; the trade-only supply constraint; the conservative scenario; the size and target of the shock; the bound on how far existing relationships may grow (the headline lets them double); and global demand with global partners. Source: `aib_node_classification.csv` (`outputs/aib` and `outputs/aib_global`); `scripts/paper/fig_aib_robustness.R`.

and trade re-optimized (the true N-1 test), coverage falls by a median of 14.5 points, and it reaches 80 percent in 28 nodes without any limit and in 25 at a 25 percent limit; in the other 63 nodes no tested limit reaches 80 percent. Diversification of existing supply does not substitute for capacity: where the N-1 test fails, the minimum required diversification does not exist and the node needs new supply.

12.6 What the analysis does and does not establish

Within the ranges explored, the within-pair rankings of ES are robust to weights, curvature and, over rankable cells, imputation, and those of EO to weights and curvature but not to imputation. The Strategic Index orders a country's sectors stably, while the allied pick, a single arg max, is robust only where its margin is large. There is no external validation: no outcome series of realised disruptions or later export growth exists against which to test the pillars, and stability shows that the rankings are determined by the data and the construction, not that they are right (Ravallion, 2012). The perturbations are local and one at a time, and several data choices are not varied: the exclusion of electricity from the grid basket and of Hong Kong's re-exports from the export measures, the treatment of non-reporting economies through mirror declarations, the rank compression of the

Table 23: Residual gap after optimized trade by technology under each variant (percent of the demand scope's traded demand), with the number of BUILD nodes in the electro-industrial scope. One setting changes at a time from the headline (China removed, hold, production-constrained, reallocation, allied demand scope). Global: every importer's demand is protected (demand scope and candidate partners global); its exposure differs from the headline's because the scope differs. Source: `allied_trade_stress_test.csv`, `aib_node_classification.csv` (`outputs/aib` and `outputs/aib_global`); `scripts/paper/fig_aib_robustness.R`.

	Headline		Release	Trade-	Conser-	China	Global demand		
Technology	Exposure	Gap		only	vative	50%	Exposure	Gap	Release
Batteries	47.5	45.2	39.4	44.8	47.5	21.5	47.8	47.8	41.1

EU's demand weight, the regional IEA 2035 manufacturing shares that every EU member inherits in the foreign-dependency and market-share variables, and the zero counted for unquantified USGS holdings. In the AIB analysis, the reference year (2024), the candidate thresholds, the classification thresholds, the curated chain links and the coalition target are not varied; the increment of the investment step is reported at 5, 10 and 20 percent but the text uses 10 percent throughout, and the classes rest on thresholds that are stated rather than estimated.

13 Discussion, next steps and conclusion

This section reads the results through the analytical design for an Allied Industrial Base of the New Energy Industrial Strategy working paper (New Energy Industrial Strategy Center, 2026), states what the paper does not establish, and sets out the extensions that design calls for.

13.1 What the results imply for an allied industrial base

Managed interdependence rather than autarky. The working paper defines the objective as managed interdependence at allied scale: strategically consequential capabilities should exist at sufficient scale somewhere in a trusted network, not in every member, because no single ally can reproduce China's scale across the electro-industrial stack (New Energy Industrial Strategy Center, 2026; Campbell and Doshi, 2025). China leads 22 of the 33 Economic Opportunity pairs and 11 of the 30 Energy Security pairs (Sections 5 and 6); a coalition member leads 16 security pairs but only 8 opportunity pairs. Within each member, opportunity and security need move in

opposite directions: the median within-country Spearman correlation between EO and $1 - \text{ES}$ is -0.49 and negative for every member (Section 9). A member's strongest opportunities lie where it is already secure, and its needs lie where others are strong. The Allied Industrial Base analysis shows what this means under stress (Section 11). With China's supply removed, the 57 members lose 22.9 percent of their traded electro-industrial demand. Existing relationships restore 7.3 points of it and optimized partnerships 0.3 more: the coordination dividend is below one point in 81 of the 91 nodes. The trade partners the allies need are already their partners; what is missing is supply.

The allied response is not new supply, either. Under the headline reading of the shock, all of the recovery, USD 232 billion in the electro-industrial scope, is drawn from buyers outside the coalition, and with every importer's demand protected nothing can be recovered by trade at all (Section 12.5). China is the largest world exporter in 9 of the 18 basket stages, including eight of the nine Midstream ones, with shares of 19 to 44 percent. The evidence that broad relocalisation is costly and that diversification usually serves resilience better than reshoring (OECD, 2025b; Thakur-Weigold and Miroudot, 2024; Aiyar et al., 2023) applies to an allied wall as much as to a national one. The stress test adds a caution about diversification itself: against a China shock a supplier-share limit costs little, but in 63 of the 91 nodes no tested limit restores 80 percent of demand after a second loss, because the capacity to diversify into does not exist.

The node, not the sector, as the unit of treatment. The working paper argues that policy should be set by node, because one technology contains very different risks (New Energy Industrial Strategy Center, 2026). The AIB analysis works at the sub-sector node, and the stages of the indices show the same heterogeneity. Technology and stage explain 44 percent of the variance of ES and 58 percent of EO, against 12 and 18 percent for countries alone, and concentration sits in different places along each chain. Midstream security is mostly a trade question (the Trade category supplies 73 percent of the Midstream score), and China is the largest exporter in almost every Midstream basket. Upstream supply is led by resource holders instead: Australia in the Batteries, Electric Vehicles and Coal baskets, Chile in Electric Grid (copper) and Kazakhstan in Nuclear. Chinese-parent ownership of foreign-invested plants is high in solar (median share 0.75 across partners) and nil in wind (Section 10). Within the electro-industrial chains, 37 of the 70 nodes need new capacity and 32 need no intervention, so a rule set by technology would treat most nodes wrongly.

Node-level treatment departs from naive rankings in two places. First, the need reading of the Strategic Index rates a stage highest where a member lacks the resource. Without the endowment screen 47 of the 57 allied picks would be Upstream, 17 of them in Nuclear Upstream, many in members with no uranium. With the screen 43 picks are Midstream, and 41 of the 57 picks change (Figure 29). The eight Nuclear Upstream picks that remain all hold identified uranium resources, but small ones (0.015 to 0.79 percent of the world's) and none with recorded mine production in 2019–2024, so they are still need-driven: the screen removes the no-resource artefact but not its small-resource counterpart. The screen is a rule of pick eligibility and leaves every index value

unchanged. Nor are the picks an allied assignment: 27 members would prioritise Batteries Midstream, but the minimum coalitions of the four compacts with a Batteries Midstream node contain 12 of them, and only 13 of the 57 members sit in a coalition for their pick stage. Second, the stress test does not follow the export ranking either: the economies that would host the most new capacity, Hungary, Czechia, the Philippines and Viet Nam, are minor suppliers of added trade, and hosts qualify on revealed capability at scale, not on their rank (Section 11.4).

Partners in the emergent network. The working paper asks an allied design to "optimize combinations, not rankings", valuing a partner for the capability it adds rather than for its stand-alone score (New Energy Industrial Strategy Center, 2026). As bilateral partners the 26 partner-tier members rank low: their median rank in the headline Partnership Strength Index is 64.5 of 192, against 16 for the core members, in part because UNGA alignment makes up on average 24 percent of the Friendshore composite. In the stress test they matter more. Partners would host 33.6 percent of the supply from the leading hosts' new capacity and economies outside the coalition 7.4 percent; Viet Nam sits in 16 of the 22 compact coalitions, more than any member; and of the six critical supply partners, two are partners (Singapore and Viet Nam) and three are outside the coalition altogether (Madagascar, Mozambique and Taiwan). Economies outside the coalition also provide 14.4 percent of the added trade. The coalition is the set of economies the analysis protects; the industrial base that supplies it is wider.

The three hypotheses. The working paper proposes three hypotheses for testing first (New Energy Industrial Strategy Center, 2026). The paper tests none of them; its results bear on each to a different degree. On the first, that allied specialisation reaches a resilience target at lower public cost than parallel national programmes, the compacts show how few countries a target needs (three to nine reach 95 percent of the anchors' traded demand in every node), but the analysis contains no costs or outlays. On the second, that coordinating demand matters more than coordinating subsidies, the results point to capacity: the trade compacts add at most 0.04 points to the system's coverage, and every compact is an investment and offtake club, which makes demand aggregation, offtake and finance rather than trade rules the instruments that matter; whether demand or subsidy coordination delivers the capacity is beyond the data. On the third, that rules targeted at high-severity nodes deliver most of the benefit of broad decoupling at lower cost, the results document a precondition, heterogeneity across nodes and stages (the Strategic Index is 73 percent sector and 4 percent country variance), but not the benefit or cost of either rule, because the stress test removes China from every node, itself a sector-wide shock.

Normative choices and how readers can vary them. The weights of the Strategic Index, its need reading, the alignment weight in Friendshore and the coalition thresholds are choices, and so are, in the AIB analysis, the economies protected, the reading of the shock and the classification thresholds. As the working paper argues, such weights are political, and analysis should display the frontier of choices rather than one number (New Energy Industrial Strategy Center, 2026). Some

choices matter a great deal (Section 12): reading the security term as strength rather than need keeps only 5 of the 57 picks; random draws of the five Strategic Index weights keep a member's pick in 73 percent of draws on average; dropping alignment from Friendshore moves China from 44th to 3rd in the Partnership Strength Index; reading the China shock as a decoupling rather than an export restriction lowers the electro-industrial nodes that need new capacity from 37 to 24. The interactive explorer that accompanies the paper exposes the index choices through four Perspective dials in its country profiles: *hawkishness* weights security (the need term, Friendshore, alignment and Chinese-parent exposure), *bullishness* opportunity (the EO term and partnership opportunity), *populism* policy signals and home manufacturing, and *greenness* climate performance, dropping coal, oil and gas at its highest settings. The paper's headline is one setting of these dials. The sector profiles show the theme data (trade flows, reserves, production, investment including the CM-FDI projects, policy records) by technology and stage without index weights, and the Allied Industrial Base section shows the stress test, the investor–host flows, the country roles and the compacts, with observed facts and settings that are preferences labelled apart.

13.2 Limitations

No outcome validation. The indices are not validated against disruptions, investment or export growth. The one predictive test, in the study of vertical complementarities (Section 12.3), is a warning: sourcing-weighted input security did not predict the import shortfalls of 2021–22, whereas sourcing concentration did. The AIB analysis is validated only by tracing four nodes through every step (Online Appendix OA.9), not against a realised shock.

Data vintages and source conventions. Inputs come from different years (92 percent of opportunity cells mix years; fossil reserves date from end-2020, mineral reserves from end-2025), and the 2020 and 2025 vintages agree less for EO (median within-pair Spearman 0.87) than for ES (0.99). Holdings the USGS does not quantify (not available, withheld or small) count as zero in the technology roll-ups. The IEA's 2035 announced manufacturing-capacity shares are regional for Europe, so every EU member carries the EU's share (for example 0.15 in Wind Midstream). The BloombergNEF outlook behind Downstream Consumption does not report Canada, whose category is imputed in all eight cells it enters, leaving six of Canada's nine scored Downstream security cells unrankable.

Mirror trade. Economies that do not report to UN Comtrade enter the trade matrix only through their partners' declarations: 65 of 208 importers in 2024, among them two coalition members (Gabon and Viet Nam). Electricity is excluded from the grid basket, and Hong Kong's re-exports from the export measures.

Traded demand and synthetic capacity. The AIB analysis covers traded demand only, so production used at home is outside it; it rests on one reference year, applies each shock node by node without propagation along the chain, reads trade values as capability except in the 11 nodes with credible physical data, and adds capacity as a standardised increment rather than as projects with costs and lead times.

Policy basis. The Policy index of 150 economies, 11 of them coalition members, rests on IEA

PAMS alone. For the 65 economies with both components, ranking their cells on IEA PAMS alone rather than on the composite gives a median within-country Spearman correlation of only 0.48.

Thin and construction-driven picks. The pick is within 0.005 of its runner-up for 10 of the 57 members and within 0.01 for 21. The Nuclear Midstream picks of Costa Rica, the Dominican Republic, Guatemala and Namibia are not an Energy Security floor effect. Each may pick only four sectors, the Midstream stages of nuclear, oil, gas and coal (Namibia also Nuclear Upstream); Midstream nuclear ES is compressed around its median; and the technology weight (0.999 for nuclear against 0.42 for gas, 0.02 for coal and 0 for oil) decides the pick. The picks reflect a narrow choice set, not an opportunity in nuclear fuel.

Coalition boundary. Taiwan (no UN vote, no listed agreement, at most 1.5 percent of any world stage) and Switzerland (whose only supplier route rested on electricity exports) are outside the coalition. The AIB analysis does not protect their demand but counts their supply: Taiwan is a critical supply partner of the battery compact.

Layers not yet measured. Of the working paper's five analytical layers, the paper measures node severity as country-relative exposure and, in the AIB analysis, as the share of traded demand a shock removes; capability through EO and revealed export capability; partner complementarity through the bilateral indices and the compacts; and robustness through the stress tests and an N-1 test. It does not measure the fourth layer, bankability, nor recovery time, common-mode risk beyond the ownership of foreign-invested plants, or the dynamic option value of latent capacity.

13.3 Next steps and recommendations

The working paper orders the decision in three steps, severity, coordination and specialisation (New Energy Industrial Strategy Center, 2026). This paper offers measured versions of the first two for traded goods and a first version of the third: the compacts name where capacity should be built and with whom. Table 24 lists ten extensions drawn from the working paper's implementation questions, analytical upgrades and research agenda, with the data and model change each requires. Five deserve emphasis.

First, a *complementarity matrix.* The AIB analysis already prices a country's marginal contribution to a compact: the leave-one-country-out test and the exact coalition identify the members no single other economy can replace. Extending the test to every economy and node, with Shapley values over the coalition program, would replace the stand-alone ranking of partners with the gap-filling value the working paper asks for.

Second, *common-mode risk and resilience floors.* Two suppliers in two countries do not diversify supply if they share a parent, a precursor or an equipment maker (New Energy Industrial Strategy Center, 2026; Farrell and Newman, 2019). The Chinese-parent component of Friendshore covers the first channel in four Midstream stages; the trade program could also cap, by constraint, the supply resting on any one parent headquarters or precursor source. The N-1 test of the stress test is a first resilience floor. Floors tied to recovery time need capacities and inventories, so that removing the largest producer for 6, 12 or 24 months yields unmet demand over time. The two other

upgrades need new inputs. *Dynamic option value*, the time and cost of ramping or requalifying capacity, calls for a multi-period version of the investment step with build lead times, which the CM-FDI announcement and completion years could calibrate. *Bankability* needs the cost of capital, permitting times, offtake and delivery capacity by country and stage (Spokas et al., 2025), entered as a host-eligibility condition or a cost of the increment.

Third, *chain pilots* for the three chains the working paper proposes: rare earths and magnets, batteries and anodes, and solar wafers. The AIB analysis already traces permanent magnets, rare-earth compounds, anode materials and wafers through every step and finds each a capacity gap under the headline, but each chain must be split into finer sub-stages (separation, alloy, magnet; graphite, spherical graphite, anode; polysilicon, ingot and wafer, cell) with plant-level capacity and qualification times. The output would be a portfolio per chain: capacity by host, minimum redundancy, priority projects and financing gaps.

Fourth, *differentiated Gates and Fences and sectoral compacts*. Combined with severity data on consequence and substitutability, the node evidence assembled here (exposure, residual gap, concentration, Chinese-parent exposure, alignment) can sort nodes into high, medium and low fences. The node table of the compacts hands each node to that evidence with its treatment, and the investor–host pairs show where development and export finance would back new capacity (Czechia, Viet Nam and the Philippines lead the most nodes).

Fifth, a *system scorecard with off-ramps*. A recurring rerun already produces several of the working paper's system metrics by node: exposure, coverage, the residual gap, the largest supplier's share and the share of supply from inside the coalition. With inventory coverage, recovery time and the price premium added, it could trigger reviews automatically, for instance when a node's residual gap rises above the BUILD threshold, and retire support when it falls.

The hypotheses can then be tested. Restricting each member to its own supply gives the self-sufficiency counterfactual for the first, once costs enter. CM-FDI project histories can be set against demand instruments and supply subsidies for the second. Shocks that remove China only in high-severity nodes, rather than in every node, would test the third, and the supplier-share frontier already shows when another supplier stops adding resilience. The study of vertical complementarities adds its own agenda (last row of the table).

13.4 Conclusion

This paper has built indices of energy security and economic opportunity for 219 economies, eleven technologies and three supply-chain stages; derived a coalition of 57 members from UN voting and supply shares; scored every ordered pair of economies as friendshoring opportunities and export markets; and stress-tested the allied supply network at 92 sub-sector nodes, from the shock through existing and optimized trade to capacity and Sectoral Compacts. The results support the working paper's premise in a limited sense: no member is both secure and competitive across the chains, and the allies' exposure to a China shock is a gap in capacity that trade among them cannot close. Whether the compacts are cheaper, more bankable or faster to recover than national programmes

Table 24: Next steps: extensions of the indices and the Allied Industrial Base analysis

Extension	Data needed	Model change
Complementarity matrix	None beyond the present inputs	Leave-one-country-out over every node and economy; Shapley values over the coalition program
Common-mode risk	Plant ownership beyond foreign investment; precursor and equipment sourcing by plant	Constraint on the supply sharing a parent headquarters or precursor source
Dynamic option value	Project lead times (CM-FDI announcement and completion years), pipeline capacity, technology readiness of substitutes	Multi-period investment step with build lead times
Bankability and feasibility	Cost of capital, permitting times, offtake, insurance, delivery capacity (Spokas et al., 2025)	Bankability as a host-eligibility condition or a cost of the increment
Resilience floors and recovery time	Demand volumes for 2030 and 2035, plant capacities, inventories	Capacities and inventories in the stress test; outages of 6, 12 or 24 months
Chain pilots	Sub-stage HS6 codes, plant-level capacity, qualification times for magnets, anodes and wafers	Sub-stage nodes for three chains; portfolio by chain
Gates and Fences by node	Consequence and substitutability by node; Chinese-parent exposure beyond four stages	Node-specific access rules for non-members
Sectoral compacts	Offtake and procurement commitments; development and export finance	Offtake volumes and finance by compact; costs of the investment step
System scorecard and off-ramps	Inventory coverage, price premium, capital mobilised	Annual rerun with review triggers on exposure and residual gaps
Vertical complementarities	Plant-level co-location; input–output coefficients; 2023 graphite and gallium controls	Coupling of supply across the nodes of a chain; tested before adoption

Notes: Extensions drawn from the implementation questions, analytical upgrades and research agenda of the NEIS working paper on the Allied Industrial Base (New Energy Industrial Strategy Center, 2026), matched to the data and model of this paper. Model changes extend the headline configuration of Section 11 (China removed, hold, production-constrained, reallocation).

needs costs, volumes and time. The indices and the AIB analysis are best read as the analytical backbone of a recurring review, with the explorer showing how its answers change when the settings change.

Appendix A Variable inventory

Tables 25 and 26 list every component of the overall variable that scores each category in `config/index_definition.yml`, for the Energy Security and Economic Opportunity pillars, as built in the final run. A final block in each table lists the configured components that no input theme of the pillar emits for a headline cell, with the reason. A category score is the mean of the listed components present in the cell (equation (15)). Index rows that a theme emits but no overall variable lists (the size and growth sub-indices of the demand composites, the level and momentum parts of the TRL Index, the two levelised-cost points, the sub-indices of the Input Cost Index) are carried for inspection and do not enter the pillars. Variables are named as in the processed theme tables and the variable-contribution tables, so every term of the decomposition of equation (20) can be traced here. Table 28 lists the inputs of the layers built on the pillars: the Policy index, the fixed terms of the Strategic Index, geopolitical alignment, the coalition rule and the partnership indices.

The columns give, for each component: its category, with the emitting theme in brackets; a one-line definition of the raw quantity, followed by the cells in which it is defined; the raw source; the transformation onto $[0, 1]$; the orientation, that is, the direction of the raw quantity that raises the index; and the missing-data rule of the emitting theme (Table 6): "zero", "avg" for the global average, or "none". $\phi_\gamma[x]_g$ is the S-curve of equation (10) with $\gamma = 0.5$ applied within the comparison set g, and ϕ^0_γ its zero-anchored variant (equation (12)); $g = (t, s)$ ranks countries within a technology-stage cell. Stages are abbreviated Up, Mid and Down, and technologies Bat (batteries), EV (electric vehicles), Grid (electric grid), H_2 (green hydrogen), Sol (solar), Wind, Nuc (nuclear), Geo (geothermal), Coal, Gas and Oil. The constructions are motivated in Sections 5 and 6; Appendix A.1 below collects the construction details of the Economic Opportunity components that the main text omits.

Table 25: Component variables of the Energy Security pillar

Variable	Category [theme]	Definition (cells)	Raw source	Transformation (S-curve group or other)	Orientation (index rises with)	Missing rule
`Mineral Supply`	Foreign Dependency [`foreign_dependency`; `critical_minerals_processing`]	Own share of world supply, and world supply concentration, of each of the technology's minerals, base year and 2035; mined at Up, refined at Mid (Up, Mid: Bat, EV, Grid, H_2, Sol, Wind)	IEA Critical Minerals Dataset: supply (base case), demand (Stated Policies)	Per mineral, mean of $\phi^0_\gamma[\sigma^{y_0}]$, $\phi^0_\gamma[\sigma^{y_1}]$, $\phi_\gamma[1-\mathrm{HHI}^{y_0}]$, $\phi_\gamma[1-\mathrm{HHI}^{y_1}]$ over all rows of the stage; 2035-demand-weighted mean over minerals (§5.2)	own share; lower concentration	avg; zero
`Market Share`	Foreign Dependency [`foreign_dependency`]	Share of world manufacturing capacity incl. announced projects (2035), world total incl. the source's "Other" row; China, Viet Nam, India, EU, US (Mid: Bat, Sol, Wind)	IEA manufacturing extract (ETP 2024)	$\phi_\gamma[\mu]$ across the five producers; every EU member carries the EU's regional share	capacity share	avg
`production`	Foreign Dependency [as above]	EV production of the country's region, 2024 (Mid: EV)	IEA EV regional data	ϕ_γ across country rows after copying regional values to members	production	avg
`sales`	Foreign Dependency [as above]	EV sales of the region, 2024 (Mid: EV)	IEA EV regional data	as above	sales	avg
`net_export`	Foreign Dependency [as above]	Net-export ratio of the region, $(P_R - S_R)/S_R$, 2024 (Mid: EV)	IEA EV regional data	as above	net exports	avg
`market_share`	Foreign Dependency [as above]	Region's share of world EV production, 2024 (Mid: EV)	IEA EV regional data	as above	world share	avg
`Production surplus/deficit`	Energy Imports [`import_dependence`]	Balance (production minus consumption, EJ) and self-sufficiency (100× production / consumption), 2025, production and consumption of the same year (Up: Oil, Gas, Coal)	EI Statistical Review; EIA International Energy Statistics for production EI does not report	Mean of $\phi_\gamma[B]_f$ and $\phi_\gamma[\beta]_f$ over the terms defined, within fuel (§5.2)	net production surplus	avg
`Oil Reserves`, `Gas Reserves`, `Coal Reserves`	Reserves [`reserves`]	Proved reserves, end-2020 (Up: Oil, Gas, Coal)	EI Statistical Review	ϕ_γ over reporting countries plus one zero anchor, anchor discarded	reserves	zero

Continued on next page

Table 25 (continued)

Variable	Category [theme]	Definition (cells)	Raw source	Transformation (S-curve group or other)	Orientation (index rises with)	Missing rule
`Batteries`, `Electric Vehicles`, `Electric Grid`, `Green Hydrogen`, `Solar`, `Wind Reserves`	Reserves [`reserves`]	Demand-weighted reserves of the technology's minerals among cobalt, lithium, graphite, rare earths, copper, manganese, nickel, zinc and PGMs, end-2025 (Up: Bat, EV, Grid, H_2, Sol, Wind)	USGS Mineral Commodity Summaries 2026 (v1.3 erratum: Brazil rare earths 11 Mt); IEA base-year demand	Per mineral ϕ_γ with a zero anchor; unlisted and unquantified (NA, W, s) holders = 0; weighted mean; ϕ^0_γ across countries (§5.2)	reserves	zero
`Nuclear Reserves`	Reserves [`reserves`]	Identified recoverable uranium resources (reasonably assured and inferred) below USD 260/kgU, 1 January 2025 (Up: Nuc)	OECD-NEA/IAEA Red Book, *Uranium 2026*, Table 1.2a	ϕ^0_γ across economies; absent = 0	resources	zero
`Overall Solar PV Potential Index`	Reserves [`solar_pv_potential`]	Total and mean photovoltaic output potential (Down: Sol)	Global Solar Atlas	$\phi_\gamma\left[\frac{1}{2}(\phi_\gamma[\mathrm{PV}^{\mathrm{tot}}] + \phi_\gamma[\mathrm{PV}^{\mathrm{mean}}])\right]$ across economies	potential	avg
`Overall Wind Potential Index`	Reserves [`wind_potential`]	Total and mean wind power density; share of area above the density threshold (Down: Wind)	Global Wind Atlas	Mean of the three ϕ_γ across economies	potential	avg
`Overall Geothermal Potential Index`	Reserves [`geothermal_potential`]	LCOE of a 500 MW and of a 5 GW enhanced-geothermal resource; total technical potential (Down: Geo)	Franzmann, Heinrichs and Stolten (2025), staged composite	Mean of three precomputed sub-indices, a missing one counted as 0	potential; lower cost	avg
`HHI`	Trade [`trade_concentration`]	Concentration of world exports of the cell's HS6 basket across reporters, Hong Kong excluded as a re-export hub (Up: Bat, Coal, EV, Gas, Grid, Nuc, Oil, Sol, Wind; Mid: all but Geo, H_2)	UN Comtrade 2024, World rows of the all-reporter pull	$\phi_\gamma[-\mathrm{HHI}]$ across the 18 basket cells of the headline technologies; one value per cell	lower concentration	avg
`market_share`	Trade [as above]	Share of world exports of the basket (same cells)	Atlas HS92 six-digit, newest year	$\phi_\gamma[\mathrm{ms}]_{ts}$ (§5.2)	export share	avg
`deficit_gdp`	Trade [as above]	Net basket imports relative to GDP (same cells)	Atlas HS92 six-digit; WDI GDP, current US dollars	$\phi_\gamma[-d]_{ts}$	smaller deficit	avg

Table 25 (continued)

Variable	Category [theme]	Definition (cells)	Raw source	Transformation (S-curve group or other)	Orientation (index rises with)	Missing rule
`Heat Pumps`, `Hydroelectric Power`, `Geothermal Reserves`	Reserves	Not produced: the IEA demand table assigns these technologies no demand for the reserve minerals.				
`Heat Pumps`, `Coal`, `Oil`, `Gas`, `Hydroelectric Power`, `Geothermal Production`	Production	Not produced by any ES theme; fossil output enters ES only through the balance of Energy Imports.				
`size`, `growth_abs`, `Overall Production`	Production	Emitted only by the EO theme `production_depth_momentum`.				
`Energy consumption per capita`, `Energy consumption per capita growth`	Consumption	Emitted under the Energy Access category, where they are scored.				

Table 26: Component variables of the Economic Opportunity pillar

Variable	Category [theme]	Definition (cells)	Raw source	Transformation (S-curve group or other)	Orientation (index rises with)	Missing rule
`market_share`	Trade [`export_feasibility`]	Share of world exports of the cell's HS6 basket (Up: Bat, Coal, EV, Gas, Grid, Nuc, Oil, Sol, Wind; Mid: all but Geo, H_2)	Atlas HS92 six-digit, newest year	$\phi_\gamma[\text{ms}]_{ts}$; identical to the ES component	export share	avg
`rca`	Trade [as above]	Balassa revealed comparative advantage in the basket (same cells)	UN Comtrade 2024: World rows of the all-reporter pull; total exports	$\phi_\gamma[\text{RCA}]_{ts}$, world over reporters in both files; Hong Kong excluded (eq. 31)	specialisation	avg
`export_size`	Trade [as above]	Value of basket exports to the world (same cells)	UN Comtrade 2024, as above	$\phi_\gamma[E]_{ts}$; a reporter without basket exports has $E = 0$; Hong Kong excluded	export value	avg
`feas`	Trade [as above]	One minus the mean Atlas distance to the basket's distinct HS4 headings (same cells)	Atlas HS92 four-digit, newest year with distances	$\phi_\gamma[\text{feas}]_{ts}$ (eq. 32)	proximity to existing capabilities	avg
`HHI`	Trade [as above]	Concentration of world basket exports across reporters (same cells)	UN Comtrade 2024	$\phi_\gamma[-\text{HHI}]$ across the 18 basket cells; identical to the ES component	lower concentration	avg
`size`	Production [`production_depth_momentum`]	Latest output: fossil production, 2025 (Up: Oil, Gas, Coal), uranium mine production, 2024 (Up: Nuc), power generation (Down: Sol, Wind, Nuc, Coal, Gas, Oil); demand-weighted share of world mined supply in the base year (Up: Bat, EV, Grid, H_2, Sol, Wind)	EI Statistical Review (EIA where EI has no row); Red Book; IEA Critical Minerals Dataset (mining rows)	Energy: $\phi_\gamma[P]_{ts}$; minerals: $\phi_\gamma[P^{y_0}]_t$ (eqs. 34, 35)	production	avg
`growth_abs`	Production [as above]	Energy and uranium: absolute change in output over five years; minerals: projected absolute change of the demand-weighted share, base year to 2035 (same cells)	as above	As for `size`	growth	avg
`Overall Production`	Production [as above]	Composite of level and growth (same cells)	as above	Energy: ϕ_γ of the mean of the level, relative-growth and absolute-growth S-curves; minerals: $\phi_\gamma[2\,\text{size} + \text{growth_abs} + h]$	production and growth	avg

Table 26 (continued)

Variable	Category [theme]	Definition (cells)	Raw source	Transformation (S-curve group or other)	Orientation (index rises with)	Missing rule
`IEA Cost index`	Cost Competitiveness [as above]	Cost of producing the equipment relative to China (= 100), 2023, six regions (Mid: Bat, Sol, Wind, H_2; Down: H_2)	IEA relative-cost estimates	$1 - \phi_\gamma[z]$ across the six regions; members take their region's value	lower relative cost	avg
`installed_cap_index`, `elec_growth_index`	Consumption [`energy_consumption`]	As in the ES pillar (Down: all but EV, Grid)	BNEF New Energy Outlook 2024	As in the ES pillar; identical values	installed base and growth	avg
Configured components emitted for no headline cell of the EO pillar						
`Cobalt` ... `PGMs Production`; `Solar` ... `Geothermal Production` (22 names)	Production	Emitted only by the ES theme `critical_minerals_production`, which is not an EO input.				
`Mineral Supply`, `Market Share`	Foreign Dependency	Emitted only by the ES themes `foreign_dependency` and `critical_minerals_processing`.				
`Energy consumption per capita`, `Energy consumption per capita growth`	Consumption	Emitted under the Energy Access category, where they are scored.				

A.1 Construction details for the Economic Opportunity pillar

Trade. Feasibility uses the Atlas distances of the newest year for which they are published, and each HS four-digit heading counts once however many of its six-digit products the basket contains. A Comtrade reporter with no exports of the basket has $E_{its} = 0$ and ranks at the bottom on export size; an economy that does not report to Comtrade has no value on export size or RCA. Country-level components are ranked across the World Bank economies within the cell; Atlas codes outside that list are excluded before ranking but kept in the world denominators.

Production: mineral block. In equation (35), $S_{im,y}$ is mined supply of mineral m by economy i in the IEA supply table (International Energy Agency, 2026a), zero where the IEA does not name i for m; W_{m,y_0} is world mined supply in the base year, named producers plus the IEA's "Rest of world"; and $\tilde{w}_{mt}$ are the IEA base-year demand shares of technology t, renormalised over the minerals with supply data. The measure is therefore a demand-weighted share of world mined supply, comparable across minerals, and growth is its absolute change to 2035 in the same units. The concentration term $h_t = \phi_\gamma[-\sum_m \tilde{w}_{mt}\mathrm{HHI}_m]$ is common to every economy of the pair and does not affect the ranking. Economies the IEA names for no mineral take the global-average fill. Solar Upstream is in effect copper, since silicon and silver have no supply rows. The fuel and uranium cells are historical instead (equation (34)): oil, gas and coal from the Statistical Review, filled from the EIA International Energy Statistics where the Review has no row, and uranium mine production from the Red Book over 2019–2024.

Technology demand. The twelve BNEF economies are Australia, Brazil, China, France, Germany, India, Indonesia, Japan, South Korea, the United Kingdom, the United States and Viet Nam; BNEF's hydrogen is all hydrogen, not only the electrolytic hydrogen that the WEO's low-emissions measure is closer to. For downstream electric vehicles, for each parameter $p \in \{\text{EV stock}, \text{EV sales}, \text{EV sales share}\}$ of passenger cars in the economies the Global EV Outlook reports (International Energy Agency, 2026d), with $v_{ip,y}$ its value (historical for 2022 and 2025, Stated Policies projection for 2035), four S-curves are ranked across countries within the parameter: the 2025 level, growth over 2022–2025, the 2035 level and growth over 2025–2035. The composite is

$$\mathrm{EVD}_i = \phi_\gamma\Big[\,\mathrm{mean}_p\,\mathrm{mean}_{\ell\in\{1,\dots,4\}}\,\phi_{\gamma_{p\ell}}(v)\Big], \tag{75}$$

and carries the name of the BNEF composite (`Overall Demand`), which has no electric-vehicle fuel, so the two never meet in one cell. The BCG addressable market covers nine technologies at three stages; its one non-positive entry, downstream batteries, marks a cell BCG does not size and is set to missing. The overcapacity ratio averages the capacity-to-demand ratios of the components of each midstream supply chain (for solar, polysilicon, wafers, cells and modules; for green hydrogen, electrolyser stacks).

Technological readiness. Items of the Clean Energy Technology Guide are mapped to a technology and a stage, or classified as out of scope, by the ordered rules of `config/iea_clean_tech_guide_tech_map.yml`, the first matching rule winning: 253 of the 634 items of the 2026 release map to a headline technology, 9 of them to more than one cell. The stage is the part of the value chain the item changes: mining and mineral extraction, fuel production sites, geothermal subsurface operations and battery recycling are Upstream; refining, fuel processing and fabrication, cells, components and equipment, and hydrogen production Midstream; power plants, complete vehicles and charging, grid operation, storage deployment and hydrogen transport and use Downstream. The Guide files oil and gas together, so their items score both. A range such as "5–6" is read as its midpoint. Items at TRL 9 are placed by the Guide's adoption stage (awaiting adoption 9, building momentum 10, commercial in many markets 11). The latest level is that of 2025, and the start level is the item's first reading among the first three years of the series. A cell's index averages its own stage's items; a stage with no item (10 of the 33 cells) takes the technology-wide value.

Input Cost Index. Upstream wages are those of mining and quarrying together with electricity, gas and water supply, or the economy-wide average where that series is not reported. The lending rate is the first available of the lending rate, euro-area rates on new and then on outstanding loans to non-financial corporations, the money-market rate, the policy-related rate and the deposit rate; mainland China, which the series does not cover, is assigned the People's Bank of China one-year loan prime rate of 3.00 per cent. A zero or negative reading in a lending-type series is a placeholder and is dropped with the averages that include it (New Zealand's lending series carries only zeros after January 2017). Wages come from the ILOSTAT copy staged on 30 September 2026. Wage and lending-rate observations more than ten years older than the newest in their panel are held out of the rankings and, for rates, of the winsorisation. Missing or held-out values are imputed within each leg from the mean of the country's World Bank region and income group, then of its income group, and finally, for wages and lending rates, from the median; on the capital side low-income economies are pooled with lower-middle-income ones, and a country with no producer-price inflation after imputation uses R_i in its place. The cost shares are those of Table 27; capital carries the larger relative weight in all but two cells, most heavily in solar and wind deployment ($0.90/0.97 \approx 0.93$ and $0.85/1.00 = 0.85$), labour the larger weight only in coal mining ($0.40/0.75 \approx 0.53$), and the two are equal in electric-vehicle manufacturing.

Equipment cost and levelised cost. The IEA relative costs are for 2023 and six regions: China, the European Union, India, Korea, other Southeast Asia and the United States. Each EU member takes the EU value and each ASEAN member on the Energy Institute's country list the value for other Southeast Asia; other economies receive the cell mean. The extract's ammonia column is assigned to downstream green hydrogen. The LCOE benchmark plants are combined-cycle gas, coal, fixed-axis photovoltaic, onshore wind and utility-scale batteries (two- and four-hour systems averaged), one asset per technology so that every market is ranked on the same asset; the reference year is 2025 in the 2026 release, and markets outside the World Bank economy list are dropped

Table 27: Labour and capital cost shares in the Input Cost Index

	Upstream		Midstream		Downstream	
Technology	α^L	α^K	α^L	α^K	α^L	α^K
Solar	0.15	0.20	0.15	0.80	0.07	0.90
Wind	0.15	0.25	0.12	0.80	0.15	0.85
Geothermal	0.15	0.68	0.12	0.80	0.22	0.70
Nuclear	0.18	0.50	0.15	0.80	0.18	0.70
Gas	0.18	0.50	0.10	0.60	0.07	0.20
Coal	0.40	0.35	0.15	0.68	0.15	0.30
Oil	0.18	0.55	0.10	0.60	0.15	0.25
Green Hydrogen	0.06	0.30	0.10	0.55	0.08	0.18
Electric Grid	0.20	0.28	0.25	0.68	0.38	0.53
Electric Vehicles	0.20	0.45	0.20	0.20	0.10	0.20
Batteries	0.22	0.45	0.08	0.15	0.08	0.30

Notes: α^L and α^K are the labour and capital shares of costs assigned to each technology and stage in `cost_competitiveness_labor_weights()` and `cost_competitiveness_capital_weights()` (`R/categories/economic opportunity/cost_competitiveness.R`). They need not sum to one, since materials and other inputs make up the remainder; the Input Cost Index uses only the relative weights $w^L_{ts} = \alpha^L_{ts}/(\alpha^L_{ts} + \alpha^K_{ts})$ and $w^K_{ts} = 1 - w^L_{ts}$ of equation (44).

before ranking.

Foreign dependency: electric vehicles. The IEA regional data report five regions that partition the world: China, the European Union, North America, other Asia-Pacific and the rest of the world. Regional values are copied to China, to the EU members, to the economies of the Energy Institute's North America sub-region, to the rest of its Asia-Pacific region, and to every other economy, European economies outside the EU included, as the rest of the world. The net-export ratio $(P_R - S_R)/S_R$ is higher for a net exporter, which is less import-dependent. The row mean `Overall Production` leaves the category score unchanged whenever all four EV indices are observed. Because the regions are coarse, the members of a region are not ranked apart on these variables, and the same holds for the EU members on the 2035 manufacturing-capacity shares.

A.2 Inputs of the policy, alignment, coalition and partnership layers

Table 28 lists the inputs of the layers built on the two pillars. Three features of the final construction deserve note. First, the Policy index has two components, IEA PAMS (required) and the Climate Action Tracker rating (added where it rates the country); the New Industrial Policy Observatory enters only a robustness variant, and a dual-use score built for earlier drafts is excluded because it takes one value for every economy of a pair. Second, the coalition is derived by rule from the U.S.–China alignment axis, GDP and two membership routes (agreements and major-supplier status), each recorded per economy, so every member's route can be traced. Third, Friendshore has

seven components: the conduit rule removes positions with sixteen financial centres from the IMF outward-investment measure, and in four Midstream cells the investment tie and the Chinese-parent exposure come from the CM-FDI project census.

Table 28: Inputs of the Policy index, the Strategic Index, alignment, the coalition rule and the partnership indices

Variable	Definition	Source	Construction and use
Policy index POL_{its} *(weights renormalised over the components present)*			
IEA PAMS component	Policies matched to technology and stage by whole-word rules; strength of a policy = product of weights for its type, status, jurisdiction and technology and stage match; summed per cell	IEA Policies and Measures, export of 22 Jan. 2026	ϕ_γ of the log of summed strength; weight 3; required (215 economies)
CAT component	Country rating $c_i \in [0,1]$ (EU members without a rating take the bloc's) combined with the technology weight g_t: $c_i g_t + (1-c_i)(1-g_t)$	Climate Action Tracker, 39 countries and the EU	Weight 2, where rated (65 economies: 39 own ratings, 26 via the EU)
NIPO component (robustness only)	Strength of industrial-policy interventions in force by jurisdiction, technology and stage	GTA New Industrial Policy Observatory, October 2026 release (in force on 5 Oct. 2026)	Not in the composite; the robustness variant adds it with weight 4 (1,070 rows, 77 jurisdictions, EU members individually)
Dual-use score (excluded)	Judgement of dual-use relevance per technology and stage, no country dimension	Project-authored	Excluded: constant within each pair, so it cannot rank economies
Fixed terms of the Strategic Index (Section 9)			
pol_{its}	Within-country S-curve of POL_{its} over the economy's in-sample sectors	Policy index	Weight 0.2
λ_s	Stage weight: Upstream 0.5, Midstream 0.75, Downstream 0.25	Project choice	Weight 0.1
g_t	Technology climate weight: min-max of minus lifecycle GHG intensity (nuclear 0.999, gas 0.42, coal 0.02, oil 0)	IPCC AR5 WGIII Annex III medians; oil from SRREN Annex II	Weight 0.1; also in the CAT component and the climate penalty of the bilateral indices
Resource base	Technology-level Reserves or Production > 0	Reserves and production themes	Eligibility of an Upstream cell for a member's allied pick; SI values unchanged
Geopolitical alignment (Section 8)			
θ_i	Mean all-votes UNGA ideal point, sessions 74–78 (2019–2023)	Bailey, Strezhnev and Voeten, Dataverse V39	193 economies with own votes
s_i	$(\theta_i - \theta_{\mathrm{CHN}})/(\theta_{\mathrm{USA}} - \theta_{\mathrm{CHN}})$, clamped to $[0,1]$	As above	U.S.–China axis
Bloc, p_i	U.S.-leaning ($s_i \geq 0.511$, $p_i = 1$), China-leaning ($s_i \leq 0.142$, $p_i = 0$), nonaligned ($p_i = 0.5$); quartile cuts	As above; territory map (project-authored)	44 territories inherit their sovereign's p_i; Taiwan, the West Bank and Gaza and Kosovo 0.5
A_{ij}	$p_i p_j + (1-p_i)(1-p_j)$	As above	Friendshore component `geo_alignment`, weight 2
Coalition rule (Section 8)			
GDP	Latest GDP, current US dollars (2025)	WDI `NY.GDP.MKTP.CD`	Floor of USD 100 billion for core members and agreement partners

Continued on next page

Table 28 (continued)

Variable	Definition	Source	Construction and use
Agreement memberships	Members of U.S. free-trade agreements, IPEF, the Minerals Security Partnership, the G7 and NATO; MSP Forum (sensitivity only)	Official lists, accessed 8 Oct. 2026 (project-authored file)	Partner route through agreements
Supply shares	World shares of production, refining, manufacturing capacity or HS6-basket exports in an Upstream or Midstream stage of a headline technology	IEA Critical Minerals Dataset; EI; Red Book; IEA ETP; Atlas	Supplier route, ≥ 5 percent, not China-leaning, no GDP floor
Reserves shares	World shares of reserves of a headline mineral, fuel or uranium	USGS MCS 2026 (end-2025); EI (end-2020); Red Book (<USD 260/kgU)	Supplier route, ≥ 10 percent
Partnership indices (Section 10)			
Bilateral trade	Reconciled flows $F_{ij,ts}$, importer first, else exporter $\times 1.06$ (equation (8)), 2020 and 2024	UN Comtrade, all-reporter dyads	S-curve of last-year level and growth (2:1) across trading dyads, then within the reporter; FS imports (weight 2), PO exports (weight 3)
Need and capability	Reporter's $1 - \text{ES}$ (FS, weight 2); partner's EO (FS, weight 2); reporter's EO (PO, weight 3); partner's $1 - \text{ES}$ (PO, weight 1)	Pillars	As built
Outbound investment	Outward direct-investment positions in debt instruments, mean of 2020–2024; positions with conduit centres unobserved	IMF Direct Investment Positions	FS, weight 2; replaced by the CM-FDI tie in Batteries, EV, Solar and Wind Midstream
Conduit centres	Netherlands, Luxembourg, Hong Kong, British Virgin Islands, Bermuda, Singapore, Cayman Islands, Switzerland, Ireland, Mauritius; Bahamas, Barbados, Turks and Caicos Islands, Isle of Man, Guernsey, Cyprus	Damgaard et al. (2024) (first ten); offshore centres	Excluded as reporters and counterparts of the IMF measure
CM-FDI investment tie	Attributed count and disclosed value of manufacturing projects of reporter-headquartered parents in the partner (joint ventures 0.5)	CM-FDI, edition of 5 Oct. 2026 (905 of 1,042 projects)	Mean of S-curves of count and value within the cell, then S-curve within the reporter
Chinese-parent exposure E_{jt}	Share of the partner's foreign-invested manufacturing in t owned by China-, Hong Kong- or Macao-headquartered parents; missing below two projects	CM-FDI	FS component scored $1 - E_{jt}$, weight 1
Climate penalty	$(1 - g_t)$ times the CAT component, scaled by a penalty weight	CAT; IPCC	Subtracted from FS and PO
Development components	WDI development and investment-environment indices, Doing Business score (2019), partner's ES and EO, supply-chain aid (absolute and per GDP), energy use	WDI; World Bank; OECD CRS	Development Potential, non-high-income partners; weights 1, 1, 1, 1, 1.5, 1.5, 2, 1

Appendix B Data sources

Table 29 lists every source the indices read, grouped as in Table 4. For each it gives the dataset and the staged file, the publisher, the coverage of the staged release, the release used by the final run and the themes and categories it feeds. Releases of pattern-resolved inputs are those selected by the rule of equation (OA.1) (Online Appendix OA.1) and recorded in the run's vintage stamp (`data/raw/raw_inputs_resolved.yml`); single staged files carry the access date recorded in the input manifest. Theme names are those of the processed tables (`data/processed/<theme>_tbl.rds`); ES and EO denote the Energy Security and Economic Opportunity pillars, FS, PO and DP the Friendshore, Partnership Opportunity and Development Potential indices. Licensed inputs are marked † (subscription) and ‡ (proprietary). Where a dataset has no bibliographic entry, the publisher's landing page recorded in the manifest is given.

Table 29: Data sources, coverage, releases used and categories fed

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
Energy statistics				
Statistical Review of World Energy, long format (`ei_stat_review_world_energy.csv`)	Energy Institute, with Ember, Kearney and KPMG (Energy Institute, 2026)	90 annual variables, 1965–2025; 142 country and region names (regional totals and the USSR dropped)	2026 (75th) edition; latest year 2025	energy_access → Energy Access (ES, EO); energy_consumption → Consumption, Energy Access (ES, EO); import_dependence → Energy Imports (ES); production_depth_momentum → Production (EO); coalition supplier test
Statistical Review of World Energy, workbook (`ei_stat_review_world_energy_wide.xlsx`)	Energy Institute	Proved reserves of oil, gas and coal (end-2020); mine production of cobalt, lithium, graphite, rare earths, copper, manganese, nickel, zinc and PGMs	2026 edition	reserves → Reserves (ES, fossil fuels); critical_minerals_production → Production (ES); coalition supplier and reserves tests
International Energy Statistics, bulk file (`eia_intl_fossil_production.csv`)	U.S. Energy Information Administration (U.S. Energy Information Administration, 2026)	Fossil-fuel production and consumption by country; oil production to 2025, gas and coal to 2024	INTL.zip of 3 Oct. 2026, accessed 11 Oct. 2026	Oil, gas and coal production where the Statistical Review has no row, as observations: import_dependence (ES), production_depth_momentum (EO)
Reserves and uranium				
Mineral Commodity Summaries 2026, world data (`MCS2026_World_Data.csv`)	U.S. Geological Survey (U.S. Geological Survey, 2026), doi: `10.5066/P1WKQ63T`	Country reserves and mine production of the nine critical minerals; holders without a figure (NA, W, s) counted as zero in roll-ups	MCS 2026, reserves at end-2025; v1.3 erratum (Brazil rare earths 11 Mt) applied	reserves → Reserves (ES, minerals); coalition reserves test

Table 29 (continued)

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
Uranium Resources, Production and Demand, Table 1.2a (`uranium_resources.csv`)	OECD Nuclear Energy Agency and IAEA (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026)	Identified recoverable resources by cost category; 59 economies below USD 260/kgU	*Uranium 2026* (NEA No. 7770), resources at 1 Jan. 2025	reserves → Reserves (ES, Nuclear Upstream); coalition reserves test
Uranium Resources, Production and Demand, Table 1.18 (`uranium_production.csv`)	OECD Nuclear Energy Agency and IAEA (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026)	Mine production by economy, 2019–2024; 18 producers in 2024	*Uranium 2026* for 2022–2024, earlier editions for 2019–2021	critical_minerals_production → Production (ES); production_depth_momentum → Production (EO); coalition supplier test
Trade				
UN Comtrade, all-reporter reporter–partner dyads in the crosswalk's products (`comtrade_energy_dyads_all.csv`)	UN Statistics Division (United Nations Statistics Division, 2026)	173 reporters in either year (168 in 2020; 142 exporting and 143 importing in 2024); 208 economies as reporter or partner; partner S19 mapped to Taiwan	2020 and 2024; main pull 7–8 Oct. 2026, supplements 9 and 12 Oct. 2026	Reconciled flow matrix (importer first, else exporter ×1.06) → FS imports, PO exports and the flows of the Allied Industrial Base analysis
UN Comtrade, energy-technology HS6 exports and imports with the world (`comtrade_energy_trade.csv`)	UN Statistics Division (United Nations Statistics Division, 2026)	World rows of the dyad pull: 142 exporting and 143 importing reporters; every current basket code (the 13 absent codes are legacy codes)	2024; derived 9 and 12 Oct. 2026	trade_concentration → Trade (ES); export_feasibility → Trade (EO): export size, Balassa RCA, export concentration (Hong Kong excluded as a re-export hub)
UN Comtrade, total exports (`comtrade_total_export.csv`)	UN Statistics Division (United Nations Statistics Division, 2026)	All-product exports by reporter	2024; pulled 9 Oct. 2026	Denominator of RCA

Table 29 (continued)

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
Atlas of Economic Complexity, HS92 six-digit country–product–year (`hs92_country_product_year_6.csv`)	Growth Lab at Harvard University (The Growth Lab at Harvard University, 2019; Hausmann et al., 2014)	1995–2023; exporter and importer reports reconciled	Latest year in the panel (2023)	World market share of the basket (ES, EO); net basket imports relative to GDP (ES); coalition supplier test; the vintage build
Atlas of Economic Complexity, HS92 four-digit (`hs92_country_product_year_4.csv`)	Growth Lab at Harvard University (The Growth Lab at Harvard University, 2019)	1995–2023; product-space distance by economy and product	Latest year with distance (2023)	Feasibility → Trade (EO)
Critical minerals				
Critical Minerals Dataset (`IEA Critical Minerals Dataset 2026.xlsx`)	International Energy Agency (International Energy Agency, 2026a)	Supply by economy for copper, cobalt, lithium, nickel, graphite and magnet rare earths (mining, refining), base year and projections; demand by technology, Stated Policies	2026 edition	Mineral weights by technology; foreign_dependency, critical_minerals_processing → Foreign Dependency (ES); production_depth_momentum → Production (EO); coalition supplier test
UN Comtrade, critical-minerals imports, exports and total exports (`critmin_import_2024.csv`, `critmin_export_2024.csv`, `critmin_total_export_2024.csv`) and partner-reported imports from non-reporters (`critmin_mirror_import.csv`)	UN Statistics Division (United Nations Statistics Division, 2026)	130, 128 and 130 reporters; 110 HS codes	2024; the 2025 pulls (3 reporters) fall below the 50-reporter floor	critical_minerals_trade → Minerals Trade (ES)
Manufacturing capacity				

Continued on next page

Table 29 (continued)

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
Clean-technology midstream manufacturing capacity (`iea_cleantech_Midstream.csv`)	International Energy Agency, Energy Technology Perspectives 2024 (International Energy Agency, 2024)	Shares of current and announced capacity for solar PV, wind, batteries and electrolysers; China, Viet Nam, India, EU, United States and "Other"; Europe reported as a region	ETP 2024	foreign_dependency → Foreign Dependency (ES); market_share_manufacturing → Foreign Dependency (EO); coalition supplier test
Electric-vehicle production and sales by region (`ev_Midstream_capacity.csv`)	International Energy Agency (Global EV Data Explorer)	China, EU, North America, other Asia-Pacific, rest of world; 2021–2024	Staged extract	foreign_dependency (ES) and market_share_manufacturing (EO), Electric Vehicles Midstream
Demand and technology				
World Energy Outlook Annex A free dataset, World (`WEO2025_AnnexA_Free_Dataset_World.csv`)	International Energy Agency (International Energy Agency, 2025b)	World totals by fuel and flow; historical and Stated Policies series	WEO 2025	future_demand → Technology Demand (EO)
Global EV Outlook country data (`EV data by country 2026.csv`)	International Energy Agency (International Energy Agency, 2026d)	73 economies and regions, 2010–2035; Stated Policies used	Global EV Outlook 2026	future_demand → Technology Demand (EO)
New Energy Outlook (`2024-10-29 - New Energy Outlook 2024.csv`)†	BloombergNEF (BloombergNEF, 2024)	Regional projections of demand, capacity and generation; Economic Transition Scenario	NEO 2024 (data file of 29 Oct. 2024)	energy_consumption → Consumption (ES, EO); future_demand → Technology Demand (EO)
Energy Transition Supply Chains (`BNEF_Energy Transition Supply Chains 2025.xlsx`)†	BloombergNEF, `https://about.bnef.com/`	Ratio of manufacturing capacity to demand by component; batteries, solar, wind, hydrogen	2025	overcapacity_premium → Technology Demand (EO)
Market Size for Technology and Supply Chain (`Market Size for Technology and Supply Chain.xlsx`)‡	Boston Consulting Group (consultancy extract)	Serviceable addressable market, United States, by technology and stage	Undated extract	future_demand → Technology Demand (EO)

Table 29 (continued)

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
UN General Assembly ideal points, all-votes series (`un_ga_ideal_points_all.csv`)	Bailey et al. (2017); Harvard Dataverse (Voeten, 2009)	Sessions 1–78 (1946–2023)	Dataverse V39.0; sessions 74–78 averaged	Alignment axis, blocs, A_{ij} (FS); coalition core and China-leaning screen
UN General Assembly ideal points, final-passage series (`un_ga_ideal_points.csv`)	As above	Sessions 1–80 (1946–2025)	Dataverse V39.0	Sensitivity of the blocs and the coalition only
Economic-security agreement memberships (`economic_security_agreements.csv`)	Project-authored from the official lists (USTR, IPEF, MSP, G7, NATO)	U.S. FTA partners, IPEF, Minerals Security Partnership and MSP Forum, G7, NATO	Accessed 8 Oct. 2026	Coalition partner route (MSP Forum as sensitivity)
Territory and non-voting economy map (`territory_sovereign_map.csv`)	Project-authored	Economies without a UN vote and the alignment each takes	Version of 8 Oct. 2026	Territories inherit their sovereign's bloc; Taiwan, the West Bank and Gaza and Kosovo neutral
World Development Indicators, development panel (`wb_wdi.csv`)	World Bank (World Bank, 2026)	Economies; 2022–2024 values used	API	DP (enabling environment, energy use)
Doing Business indicators, historical (`wb_doingbusiness.csv`)	World Bank (World Bank, 2020); discontinued (World Bank Group, 2021)	190 economies; ease-of-doing-business score, 2019	Doing Business 2020 release	DP (business environment)
Creditor Reporting System, aid flows (`oecd_crs_api.csv`)	OECD, `https://data-explorer.oecd.org/`	ODA disbursements by donor, recipient and sector, 2013–2024	Staged extract; summed over years	DP (aid by stage)
World Development Indicators, GDP in current US dollars, `NY.GDP.MKTP.CD` (`wdi_gdp.csv`)	World Bank (World Bank, 2026)	2007–2025	Pulled at ingestion	Net imports relative to GDP (ES Trade); coalition GDP floor; scaling of investment and aid in the bilateral indices
WDI country reference table (`wdi_country_info.csv`)	World Bank (World Bank, 2026)	217 economies and 79 aggregate codes; Taiwan added by the pipeline	Pulled at ingestion	Canonical economy names; comparison sets of the trade, cost and LCOE themes (Section 3.4)

Continued on next page

Table 29 (continued)

Dataset (staged file)	Publisher	Coverage of the staged release	Release used	Themes → categories fed
State System Membership List	Correlates of War Project (Correlates of War Project, 2024)	195 states in 2024 (UN members, Kosovo, Taiwan)	v2024, accessed 7 Oct. 2026	Sovereignty condition of the rankability rule
Project-authored crosswalks and lists				
Energy HS6 master catalogue (`data/reference/energy_hs6_master.csv`) and its generated views	Project-authored	259 HS6 codes in 415 basket rows (17 legacy bridge codes); Upstream and Midstream; excluded rows kept with their reasons	Repository version after the October 2026 review	Trade baskets of both trade themes, the bilateral trade components and the AIB nodes (Section 3.2)
Conduit financial centres (`config/partnership.yml`)	Project-authored after Damgaard et al. (2024)	16 economies: 10 pass-through economies and 6 offshore centres	Repository version	Exclusion from the IMF outward-investment measure of FS

Notes to Table 29. Coverage describes the staged release files, before harmonisation; the number of economies scored after harmonisation is reported in Figure 3. Two bookkeeping files complete the manifest: the Comtrade retrieval stamp and the vintage stamp of resolved releases. Inputs that the final indices do not read are not listed: the dual-use scores, which are excluded from the Policy index because they take one value for every economy of a technology–stage pair; the February, June and July 2026 NIPO extracts (the October 2026 run is used for the robustness variant); the earlier direct Comtrade extract of energy-technology trade and the 22-reporter allied dyad pull, both replaced by the all-reporter pull; a USGS Mineral Commodity Summaries 2025 file; and staged releases of pattern-resolved inputs that the rule does not select. The IPCC values are those of the Fifth Assessment Report, except the oil-fired value, which is taken from the Annex II of the Special Report on Renewable Energy Sources.

Appendix C Allied Industrial Base: formulations

This appendix states the programs behind Section 11. The functions of `R/aib/` read and write no files; all input and output is in `scripts/31_build_aib_trade_network.R` and `scripts/32_build_aib_partnerships.R`, and every setting is in `config/aib.yml` (Table 30). Every program is solved with GLPK (Makhorin, 2020).

C.1 The node problem

Fix a node n and a shock. Let $v_{em} \geq 0$ be the reconciled 2024 flow from exporter e to importer m (USD; flows under USD 10,000 are not relationships), $W = \sum_{e,m} v_{em}$ world trade in the node, $\rho_e \in [0,1]$ the fraction of e's supply removed (1 for China, Hong Kong and Macao under the headline) and X the shocked economies. The demand scope is $M = \{m \in \mathcal{M}_0 \setminus X : \sum_e v_{em} > 0\}$, where $\mathcal{M}_0$ is the configured set (the 57 coalition members), and the candidates are

$$E = \Big\{ e \in \mathcal{E}_0 \setminus X : \ \textstyle\sum_m v_{em} \ \geq \ \max\{10^6, \ 5 \times 10^{-4}\, W\} \Big\}, \tag{76}$$

with $\mathcal{E}_0$ the candidate universe (every economy less the open ship registries). All quantities are divided by the scope's demand $D = \sum_{m \in M} \sum_e v_{em}$, so that coverage is a share of D. For $m \in M$ let $d_m = \sum_e v_{em}/D$ and

$$F_m = \frac{1}{D} \sum_{e \notin E} (1 - \rho_e)\, v_{em}, \qquad F = \sum_{m \in M} F_m, \qquad L = \frac{1}{D} \sum_{m \in M} \sum_e \rho_e v_{em}, \tag{77}$$

the shipments of non-candidates, which stay where they are, and the lost supply; shock exposure is L and the static coverage of state A is $C^{\mathrm{A}} = 1 - L$. For a candidate e, $b_{em} = v_{em}/D$ is its current shipment to $m \in M$, $b_e = \sum_{m \in M} b_{em}$, o_e its exports to markets outside $M \cup X$ and

$\phi_e = \sum_{x \in X} \rho_x v_{ex}/D$ the supply freed by a release shock ($\phi_e = 0$ under hold). Its available supply is

$$a_e = \min\Big\{ b_e + \phi_e + \mathbf{1}[\text{reallocation}]\, o_e, \quad \bar{a}_e \Big\}, \qquad \bar{a}_e = \begin{cases} S_e/D & \text{if } e \text{ is a listed producer,} \\ b_e & \text{if not,} \end{cases} \tag{78}$$

where S_e is e's world exports in the node and $\bar{a}_e = \infty$ in nodes without credible physical data or in the trade-only mode. A listed producer has a production or capacity share above zero in a proxy that covers at least 80 percent of world output.

C.2 The trade program (states B and C)

The decision variables are flows $f_{em} \geq 0$ on an arc set $\mathcal{A}$: in state C, every pair $E \times M$; in state B, the observed relationships $\{(e,m) : b_{em} > 0\}$ plus (e,e) for candidates in the scope (keeping exports at home). In the reallocation scenario each surviving relationship $k = (e,m)$ with $b_k > 0$ also carries a cut $u_k \geq 0$. With a maximum supplier share κ (the headline has $\kappa = 1$; the frontier uses 0.25, 0.40 and 0.60) and the growth bound η of state B ($\eta = 1$), the feasible set is

$$\begin{aligned}
&\textstyle\sum_m f_{em} \leq a_e && \forall e \in E, && \text{(79a)}\\
&\textstyle\sum_e f_{em} \leq d_m - F_m && \forall m \in M, && \text{(79b)}\\
&f_{em} \geq b_{em} && \text{(conservative)}, && \text{(79c)}\\
&u_k \geq b_k - f_k, \quad 0 \leq u_k \leq b_k && \text{(reallocation)}, && \text{(79d)}\\
&f_{em} \leq (1+\eta)\, b_{em} && \text{(state B, } b_{em} > 0), && \text{(79e)}\\
&\textstyle\sum_m f_{em} \;\leq\; \kappa \left(F + \sum_{e',m} f_{e'm}\right) && \forall e \in E \text{ (if } \kappa < 1). && \text{(79f)}
\end{aligned}$$

Where a supplier's locked shipments already exceed κ of the locked total, its flows are fixed at their lower bounds instead of (79f). Coverage is $C = F + \sum_{e,m} f_{em}$. The program is solved lexicographically: with objectives

$$z_1 = \sum f_{em}, \qquad z_{1b} = -\sum_k u_k, \qquad z_2 = \sum w_e f_{em}, \qquad z_3 = \sum \mathrm{PO}_{em} f_{em}, \qquad z_4 = \sum \chi_{em} f_{em}, \tag{80}$$

step j maximizes z_j subject to (79) and to $z_i \geq z_i^* - \max\{\epsilon_i |z_i^*|, 10^{-9}\}$ for every earlier step i, with tolerances $\epsilon_1 = 5 \times 10^{-4}$, $\epsilon_{1b} = 10^{-6}$ and $\epsilon_2 = \epsilon_3 = 0.02$. The specialization weight is $w_e = \max\{\min(\mathrm{RCA}_e, 4)/4,\ \pi_e\} + 10^{-3}\sigma_e$, with π_e the production share where a proxy exists and σ_e the world export share; PO_{em} is Export Opportunity from e to m and χ_{em} the mean of the available policy and climate similarities; missing scores are 0.5, and a domestic arc scores 0.5 on PO and 1 on compatibility. The coordination dividend is $C^{\mathrm{C}} - C^{\mathrm{B}}$ at $\kappa = 1$; diversion is $\sum_e \max\{0, \sum_m f_{em} - b_e - \phi_e\}$.

Closed form of state C. In state C every candidate reaches every importer, so the program decomposes at the exporter level: coverage is the largest T with

$$T \;\le\; F + \sum_{e \in E} \min\{a_e,\; \kappa T\} \qquad \text{and} \qquad T \;\le\; F + \sum_{m \in M} (d_m - F_m), \tag{81}$$

found by bisection since the gap between the two sides is concave in T; the stability step then keeps surviving shipments up to the limit and the specialization step fills the rest from the exporters with the highest w_e. Objectives 3 and 4 decide only which importer each unit goes to. The closed form agrees with the LP on coverage and exporter totals (unit tests) and is used for the frontier, the investment simulation and the coalition test; the LP is solved where the importer allocation is reported.

Frontier and N-1. For each $\kappa \in \{0.25, 0.40, 0.60, 1\}$ the frontier records coverage, concentration and two N-1 readings: the instantaneous one, $C\,(1 - s_{\max})$ with $s_{\max}$ the largest supplier's share of the optimized supply, and the re-optimized one, in which the largest remaining supplier is removed from the problem (its shipments become lost supply and it ceases to be a candidate) and state C is solved again at the same κ. The tightest costless limit is the smallest κ whose coverage is within two points of the unconstrained optimum; the minimum required diversification is the loosest κ at which the re-optimized N-1 coverage reaches 80 percent (none if no tested limit reaches it).

C.3 The investment step

A node enters the simulation under a shock if its residual gap $1 - C^{\mathrm{C}}$ is at least 5 percent. Host h is eligible if it is a candidate universe member outside the open registries and satisfies at least one of: $\mathrm{RCA}_h \ge 1$ on exports of at least USD 50 million or 1 percent of W; a production share of at least 1 percent; a world export share of at least 0.5 percent; or $\mathrm{RCA}_h \ge 1$ at that scale in a node joined to n by a material link. The increment $\delta \in \{0.05, 0.10, 0.20\}$ (the headline is 0.10) is added to a_h (a host that is not a candidate joins the program with δ only), and state C is re-solved:

$$g_h(\delta) = C^{\mathrm{C}}(a + \delta\,\mathbf{e}_h) - C^{\mathrm{C}}(a), \tag{82}$$

both at $\kappa = 1$ and at the diversified limit $\kappa = 0.40$. Without a limit every host's gain is $\min\{\delta, 1 - C^{\mathrm{C}}\}$, so hosts are ordered by g_h at $\kappa = 0.40$, then by the fall in the Herfindahl index of supply, then by capability tier and value (the larger of the host's world export share and production share), then by Friendshore from the importers that lost supply, weighted by their loss, then by policy compatibility; gains within 0.5 points of the best and Herfindahl changes within 0.005 of the lowest are ties. For the five best hosts at $\delta = 0.10$, with every other flow fixed at the optimized allocation, the lexicographic optimum of the new capacity is greedy: it fills the importers' unmet demand $d_m - F_m - \sum_e f_{em}$ in descending PO_{hm}, then compatibility. Each importer served is an investor of the pair (m, h); the emergent network keeps the first-ranked host only, turned round as $h \to m$.

C.4 Grouping and the exact minimum coalition

Grouping. For intervention nodes n, n' in the strategic scope, the distance is $1 - \mathrm{sim}_{nn'}$ if the pair passes chain coherence (one node within three directed links of the other in the curated chain, or both feeding the same node directly) and policy coherence (cosine similarity of the need profiles at least 0.5), and 10 otherwise, where $\mathrm{sim}_{nn'}$ is the larger of the cosine similarity of the nodes' recurring supplier vectors and of one node's suppliers with the other's buyers. Complete-linkage clustering cut at $1 - 0.35$ gives groups in which every pair passes, and each group is split into the connected pieces of the chain (linking through nodes that belong to no group).

Anchors and coverage. The demand anchors A are the importers holding 60 percent of the group's lost supply, at most six. In node n, with $d_n^A = \sum_{m \in A} d_m$, the anchors' coverage when the members S coordinate is

$$C_n^A(S) = \min\Big\{1,\ (F_n^A + \textstyle\sum_{c \in S} g_{nc})/d_n^A\Big\}, \tag{83}$$

where F_n^A is what reaches the anchors with nobody coordinating (non-candidates' shipments and every candidate's current shipments to them) and g_{nc} what candidate c adds by coordinating: in the reallocation scenario $\max\{0, a_c - b_c^A\}$, its available supply less its current shipments to the anchors; in the conservative scenario its freed supply within its physical room; plus $\delta = 0.10$ if c is one of the two leading hosts of a node that needs capacity.

The binary program. With $y_c \in \{0, 1\}$ for every candidate and the target τ (the headline is 0.95; 0.90 and 0.99 are also solved),

$$k^* = \min_{y} \ \textstyle\sum_c y_c \tag{84a}$$

$$\text{s.t. } F_n^A + \textstyle\sum_c g_{nc}\, y_c \ \geq\ \tau\, d_n^A \qquad \forall n \in \text{group}, \tag{84b}$$

$$y_c = 1 \qquad \forall c \in A. \tag{84c}$$

The coverage cap in (83) does not bind at a target below one, so the program is exact. The robust tie-break then solves

$$\max_{y,\zeta}\ \zeta \quad \text{s.t.} \quad \frac{F_n^A + \sum_c g_{nc} y_c}{d_n^A} - \zeta\ \geq\ \tau\ \ \forall n, \qquad \textstyle\sum_c y_c = k^*, \qquad y_c = 1\ \forall c \in A, \qquad 0 \leq \zeta \leq 1 - \tau, \tag{85}$$

the largest smallest margin over the target among coalitions of the minimum size, and a third program maximizes $\sum_n \sum_c g_{nc} y_c / d_n^A$ with ζ held at its optimum. Each solve has a time limit; a solve that reaches it keeps its best feasible solution and is reported. Where even every candidate cannot reach τ in some node, the coalition is the widest greedy set and is labelled so.

Tiers. For each member c of the 95 percent coalition S^*, c is needed if $\min_n C_n^A(S^* \setminus \{c\}) < \tau$ with c's supply removed; it is a critical supply partner if, in addition, no single non-member c' restores the target, $\min_n C_n^A(S^* \setminus \{c\} \cup \{c'\}) < \tau$ for every c'. The associates solve (84) at $\tau = 0.99$ with S^* held in. A non-member x is a critical external dependency if removing its current shipments to the anchors pushes some node below τ with S^* fixed (or, where a node is already below it, lowers its coverage by a point or more) and it supplies at least 1 percent of the anchors' demand. A group is a candidate compact if $\min_n C_n^A(S^*) - C_n^{A,\mathrm{B}} \geq 0.05$ for its anchors' existing-relationship coverage $C^{A,\mathrm{B}}$, and a bilateral arrangement if $|S^*| < 3$.

Table 30: Settings of the Allied Industrial Base analysis (headline configuration)

Setting	Value	Role
Reference year	2024	Flows, RCA and world shares
Demand scope	57 coalition members	Importers whose lost supply is restored
Candidate partners	all economies; $\geq$ USD 1m and 0.05% of world exports	Exporters that may adapt
Shock (headline; others)	China 100%, hold; China 50%, largest supplier, release	Supply removed; whether China keeps buying
Supply scenario	reallocation; conservative	Whether exports outside the scope can move
Supply constraint	production-constrained; trade-only	Physical data decide who can supply
Physical data	proxy $\geq$ 80% of world output; divergence 25 points	Listed producers; warning
Growth bound η (state B)	1 (sensitivity 0.25, 3, ∞)	Existing relationships may double
Tolerances	coverage 5×10^{-4}; stability 10^{-6}; others 0.02	Lexicographic steps
RCA cap	4	Specialization weight
Maximum supplier share κ	1 (frontier 0.25, 0.40, 0.60)	Diversification limit
N-1 acceptable coverage	0.80	Minimum required diversification
Investment	gap $\geq$ 5%; $\delta \in \{0.05, 0.10, 0.20\}$; $\kappa = 0.40$ for ranking; 20 hosts	Marginal capacity
Classification	exposure 15%; gap 10%; dividend 5 pts; existing 90%; shares 40%, 75%; cost 5 pts	Node treatment
Grouping	3 chain hops; partner similarity 0.35; policy similarity 0.5	Compact formation
Coalition	anchors 60% of loss (≤ 6); $\tau = 0.95$ (0.90, 0.99); compact gain 5 pts; ≥ 3 members	Exact coalition and tiers
Strategic scope	electro-industrial (70 nodes)	Compacts and network edges

Notes: Every setting is in `config/aib.yml`; command-line flags of `scripts/32` override the demand scope, the candidate universe and the strategic scope.

Appendix D Corrections relative to the shipped release

The indices were first released in September 2026. That *shipped release* combined artefacts built at different dates: the Energy Security and Economic Opportunity pillars and the Strategic Index of 3 September 2026 rested on a policy component table of 6 February 2026, the partnership tables dated from 24 March 2026 and the allied network outputs from 23 February 2026. Before the results of this paper were produced, the pipeline was audited end to end, from the staged raw inputs to the

published tables, and every defect found was corrected. A set of data and method changes followed, decided while the paper was written. All index results in Sections 5–12 come from one complete run of the corrected pipeline, the final run of 12 October 2026, built from a single revision of the code; the Allied Industrial Base analysis of Section 11 was run on the inputs of that run on 16 October 2026. This appendix lists every correction and change and compares the shipped release with the final one, so that a reader who holds numbers from the shipped release can tell which changed and why.

D.1 Scope and kinds of change

Table 31 gives one line per item. The items coded A to N are defects. They fall into three kinds. *Input defects* change what a variable measures: a join on mismatched keys, a wrong supply-chain stage, a ranking taken over the wrong population. *Aggregation defects* change how correctly measured variables are combined: an unobserved category scored as zero, a row counted several times. *Reporting defects* leave every value unchanged but misstate a diagnostic, a label or the documentation. The distinction matters for reconciliation: reporting defects change no number, aggregation defects mostly shift the levels of whole cells, and input defects can reorder countries within a cell. The uncertainty and sensitivity analyses recommended for composite indicators vary weights, normalisation and aggregation for given inputs (Saisana et al., 2005; Nardo et al., 2008); they can reveal the second kind of defect but not the first, which is why the audit traced each variable from its source to the index.

The items coded D (data) and M (method) are not defects. They are changes of source, basket or design adopted after the audit, most of them by explicit decision, and they are described in the main text where they apply. For each defect the audit re-ran the affected builders on the inputs saved with the shipped release and compared the outputs. These *pre-rerun effects*, reported in Online Appendix OA.11 with the symptom and the correction of each item, isolate one correction on inputs that still embed the others; they are not results of the paper. Each correction comes with unit tests that encode the corrected behaviour, and the code in `R/`, `scripts/` and `config/` is its specification.

Table 31: Index of corrections and changes relative to the shipped release

Item	Correction or change	Commit	Outputs affected	Status
Aggregation				
A1	Available-case aggregation: an unobserved category no longer counts as zero	`7003d11`	ES, EO, PSI	R
A2	Imputation only in groups with an observed country	`7003d11`	ES, EO	L
A3	Imputed flag for groups with several components	`7003d11`	ES, EO diagnostics	D
A4	Energy Prices scored; guards for unproduced score variables	`7003d11`, `cd3b6cc`	ES, EO Upstream	R

M4	Endowment screen for the allied pick	`0aaf68d`	allied pick	X
M5	Alignment in Friendshore; conduit centres out; core-view PSI	`6ef4831`	FS, PSI	X
M6	Network on Upstream and Midstream, diversification term, caps, no policy term (retired)	`5afe34c`	network	X
M7	Calibration rule for λ; $\lambda = 0.78$ on the final inputs (retired)	`3122cea`	network	X

Notes: Status R: the defect changed values in the shipped release. L: latent; it did not change the shipped release but would have changed a rerun. D: diagnostics, labels or documentation only. X: change of data or method adopted after the audit, not a defect. Commits are on branch `fix/allied-base-paper`; the audit corrections (`7003d11` to `cd3b6cc`) were applied to revision `c0cd1ce`. Item detail: Online Appendix OA.11.

D.2 The main corrections

Four defects account for most of the difference between the releases, and each is stated here formally. Write c_{itsk} for the score of category k in cell (i, t, s), w_k for its weight and R_{its} for the categories with a row for the cell, observed or not.

Unobserved categories as zeros (A1). The shipped builder kept an unobserved category in the denominator,

$$I^{\text{shipped}}_{its} = \frac{\sum_{k \in R_{its}} w_k \, c_{itsk} \, \mathbf{1}[c_{itsk} \text{ observed}]}{\sum_{k \in R_{its}} w_k}, \tag{86}$$

so it counted as zero and a cell with no observed category scored zero. The corrected pillar is the available-case mean,

$$I_{its} = \frac{\sum_{k \in R_{its}} w_k \, c_{itsk} \, \mathbf{1}[c_{itsk} \text{ observed}]}{\sum_{k \in R_{its}} w_k \, \mathbf{1}[c_{itsk} \text{ observed}]}, \tag{87}$$

and a cell without an observed category is missing (Section 4). Combined with the zero cells that the investment theme manufactured (E7), the shipped rule made Energy Security in Nuclear Upstream zero for every economy, so its security need was maximal everywhere and it was the top allied pick of 8 of the 18 shipped allies.

Market share of a basket (T3). The shipped trade theme averaged a country's product-level world shares with its own exports as weights, which measures dominance in the products it ships rather than weight in the basket:

$$\widetilde{ms}_{its} = \frac{\sum_{h \in B_{ts}} X_{ih} \, (X_{ih}/W_h)}{\sum_{h \in B_{ts}} X_{ih}}, \qquad ms_{its} = \frac{\sum_{h \in B_{ts}} X_{ih}}{\sum_{h \in B_{ts}} W_h}, \tag{88}$$

with X_{ih} exports of product h, W_h world exports and B_{ts} the basket. The corrected measure is ms_{its}.

In the shipped Batteries Midstream basket the Democratic Republic of the Congo had $\widetilde{ms} = 0.862$ against a basket share of 0.0074. Together with the ranking of export size across economies rather than within each reporter (T2), the correction changes the ten leading EO Trade scores in Batteries Midstream, on the shipped inputs, from ore exporters (Chile, Peru, Zimbabwe) to cell and material manufacturers (China, Germany, the United States). The ES and EO trade themes had, moreover, been identical tables (T1).

The PSI denominator (B4). Development potential is defined only for partners that are not high-income, but for a high-income partner it kept its weight and contributed nothing,

$$\mathrm{PSI}_j^{\mathrm{shipped}} = 0.4\, C_j^{\mathrm{FS}} + 0.4\, C_j^{\mathrm{PO}} \;\leq\; 0.8, \tag{89}$$

so high-income partners sat at the bottom: the United States ranked 185th of 218. With the duplication of Friendshore rows (B1) and the outbound-investment defect (B2), the shipped PSI ordering does not survive the corrections.

The remaining defects are smaller but not negligible. The country standardiser left 30 economies under two or three spellings, each taking its own rank in every S-curve (C1); graphite and the rare earths fell out of every mineral join (E1); refining was pooled with mining (E2); and the policy block had not written its table since February 2026 (P4), with substring stage rules that tagged 37 percent of IEA policies Upstream (P2). Three latent defects (A2, A7, C3) would have changed a rerun; A7 alone would have removed every category built from an overall score. Item E12 is a defect found late: an economy without its own production row in the Energy Institute's tables (Energy Institute, 2026) was read as producing nothing, so New Zealand counted as importing all its gas. Its production now comes from the EIA (U.S. Energy Information Administration, 2026).

D.3 Data and method changes

The data changes replace or extend sources. Nuclear Upstream, which the shipped release scored on a manufactured zero and the audited code on the world uranium price alone, is scored on the identified resources and mine production of the OECD-NEA/IAEA Red Book (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026) (D1). Critical-mineral reserves come from the USGS Mineral Commodity Summaries 2026 (U.S. Geological Survey, 2026) rather than the older USGS figures repeated in the Energy Institute's sheets (D6). Technological readiness is mapped by stage from the IEA Clean Technology Guide (International Energy Agency, 2026c) (D2). Bilateral trade comes from all-reporter Comtrade dyads, importer report first, else the exporter's mirror declaration times 1.06 (D3). The HS6 baskets were reviewed against a dominant-use rule, which removed 92 basket rows; electricity left Electric Grid Upstream, which received a copper and aluminium input basket, telecommunications switching equipment left Electric Grid Midstream, and five technologies received Upstream baskets (D4, D5, D7, D9). Hong Kong left the Comtrade export measures as a re-export hub (D7). Friendshore gained investment ties and a Chinese-parent exposure component from the CM-FDI project data (Bandara and Net Zero Industrial Policy Lab, 2026)

(D10). One limitation of the sources remains: the IEA's 2035 announced manufacturing-capacity shares are regional for Europe, so every EU member carries the EU's share in the variables built on them (Section 13.2).

The method changes are the rankability rule (M1); the coalition derived from UN-voting alignment in two tiers, with the EU-27 as one unit (M2), which replaced the shipped hand-picked list of 23 economies; a Policy index built on IEA PAMS, combined with CAT where CAT rates the country, which dropped the GTA NIPO component and the dual-use score of the shipped four-component index (M3; NIPO survives only as a robustness variant, rebuilt from the October 2026 extract for 77 jurisdictions); the endowment screen of the allied pick (M4); the alignment component, the exclusion of conduit financial centres and the core-coalition view of the PSI (M5); and the changes M6 and M7 to the network design, which the paper no longer uses.

The retired network design. The shipped release and earlier drafts of this paper allocated production among the coalition's units with a network design (`scripts/30_build_allied_network_design.R`): for each Upstream and Midstream stage, a mixed-integer program over 37 units (the EU-27 as one, its members' inputs combined with stage-specific weights: production, else HS6-basket exports, else GDP) chose producers, links and flows to maximise an index-based score of producer capability and partnership edges less a concave penalty on the Herfindahl index of designed shares, under share bounds, a dual-sourcing floor and GDP-log portfolio caps (M6), with the penalty weight set by a rule, the smallest λ whose median designed Herfindahl index does not exceed the units' median observed export concentration (M7; 0.78 on the final inputs). Its shipped outputs carried no usable information: the node table joined the dyadic development table without aggregating it and the greedy solver filled producer slots with rows rather than countries, so one country could appear as k^2 producers with a Herfindahl index of one (606,866 specialisation rows, 2,339 distinct), with transposed edges, counts over rows and an invalid code for the United Arab Emirates (N1–N7). The corrected design was then replaced by the Allied Industrial Base analysis of Section 11, because it scored capability rather than observed supply, measured neither shocks nor what existing trade can absorb, and rested on a calibrated weight that met its target by a knife-edge margin. Its code remains in the repository outside the pipeline run, and no result of this paper depends on it.

D.4 Reconciliation with the shipped release

Matching and coverage. The comparison uses the headline tables of the two releases. Every shipped country name is mapped to its canonical name (C1), units without an ISO3 code are dropped (C2), and where two spellings give the same key the record under the canonical spelling is kept. Harmonisation alone reduces the shipped Energy Security table from 270 strings to 237 economies, merging 162 rows of 29 economies that appeared under two or three spellings. Table 32 reports the counts. Of the harmonised ES cells 5,522 are in both releases; 710 are new in the final one, mostly economies reached by the rebuilt trade themes and the Green Hydrogen Midstream cells the shipped ES did not score. For EO, 6,598 cells are in both and 533 are new, mostly imputed

(median imputed weight share 0.68) and only 11 rankable.

Three rules apply to the pillar statistics. A technology–stage cell in which a pillar is constant in either release is excluded: this removes ES in Nuclear Upstream, zero for every economy in the shipped release, and the shipped Geothermal Upstream and Midstream cells. Rank statistics are computed over the cells rankable in the final release (Section 4), with statistics over all matched cells alongside. Correlations are Spearman unless labelled otherwise. Table 33 summarises the agreement.

The pillars. Over the rankable matched cells the Spearman correlation between the releases is 0.81 for ES and 0.67 for EO (Figure 45). Agreement differs by stage in opposite directions: for ES it is lowest in the Midstream (pooled 0.55), where the Trade category was rebuilt from all-reporter dyads and reviewed baskets; for EO it is lowest in the Upstream (0.50), where categories enter the cell and Trade and Investment were rebuilt. Levels moved as well as ranks: the mean change is +0.021 in ES but +0.081 in its Upstream, partly because 89 Upstream cells of 21 economies scored exactly zero under rule (86). A change of more than 0.1 affects 31 percent of rankable ES cells and 17 percent of EO cells.

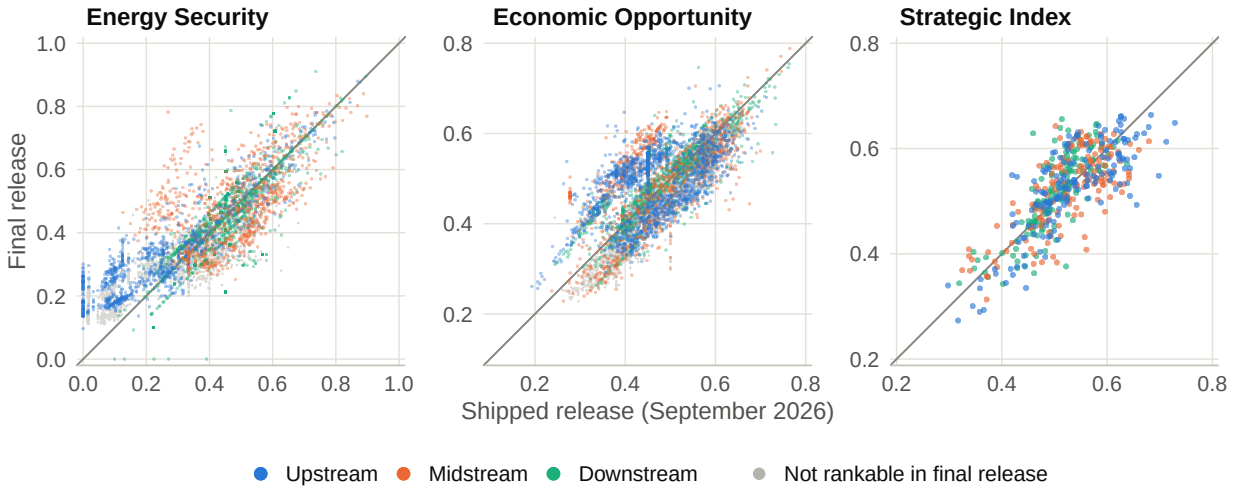

Figure 45: Shipped against final release, cell by cell. Each point is a country–technology–stage cell (Energy Security, Economic Opportunity) or a country–sector cell (Strategic Index) present in both releases, with the shipped value (3 September 2026) on the horizontal axis and the final value (12 October 2026) on the vertical axis. Colour marks the stage of cells rankable in the final release (sovereign economy, at most half of the index weight imputed); grey points are matched cells that are not rankable. Energy Security: 5,305 matched cells, 3,537 rankable; Economic Opportunity: 6,598 and 4,290; Strategic Index: the 477 cells of the 18 economies of the shipped hand-picked list scored in both releases. Technology–stage pairs in which a pillar is constant in either release are excluded. Spearman correlations over rankable cells: 0.81, 0.67 and 0.74. Shipped names are mapped to canonical names before matching (item C1). Sources: `index_outputs.rds` of the two releases; `scripts/paper/fig_reconcile.R`.

A pooled correlation mixes level shifts of whole cells with reorderings within them. Figure 46 separates the two. The median within-cell correlation is 0.83 for ES and 0.77 for EO; 45 percent of

Cells in both releases	477	477

Notes: Headline tables of the eleven technologies. Shipped release: `index_outputs.rds` of 3 September 2026; final release: the same file of the final 12 October 2026 run. Shipped country names are mapped to canonical names with `standardize_country_names()` (item C1); units without an ISO3 code ("Global", "USSR", "Northern Cyprus") are dropped (item C2) and, where two spellings give the same cell, the record under the canonical spelling is kept. "Rankable": the economy is sovereign and at most half of the cell's index weight is imputed (`config/rankability.yml`); the shipped release had no such rule. "Cells in one release only" counts shipped cells absent from the final release (first column) and final cells absent from the shipped release (second column). A Strategic Index cell of the final release requires a Policy index (IEA PAMS, combined with CAT where CAT rates the country) and a rankable EO and ES value; a shipped cell required the four-component Policy index of February 2026 and imputed missing pillar values (item P7).

Table 33: Rank agreement between the shipped and the final release

		Pooled Spearman		Median within-cell Spearman			
Index	Units in both	Rankable	All	All	Up	Mid	Down
Energy Security (ES)	3,537 cells	0.81	0.84	0.83	0.84	0.70	0.90
Economic Opportunity (EO)	4,290 cells	0.67	0.71	0.77	0.61	0.80	0.88
Strategic Index (SI)	477 cells	0.74	–	0.74	–	–	–
PSI, world view	187 partners	−0.09	–	–	–	–	–
PSI, core view	191 partners	−0.33	–	–	–	–	–

Notes: Units present in both releases after harmonising shipped country names (C1) and dropping non-country units (C2). ES and EO: rankable matched cells of 194 and 178 economies, technology–stage cells constant in either release excluded; "All" pools every matched cell (5,305 ES, 6,598 EO). Within-cell correlations are across economies within a technology–stage cell (28 ES and 33 EO cells; medians by stage); for the SI they are across sectors within each of the 18 economies of the shipped list scored in both releases (range 0.42 to 0.92). The shipped PSI is reconstructed from the March 2026 partner tables with the shipped code's logic (B4) and compared with the final world view (like for like) and with the headline core view. Source: `paper/results/reconcile.json`.

ES values and 56 percent of EO values move by more than ten places in their cell (median moves of 9 and 13 places). A two-factor Shapley decomposition of each cell's change, with an unobserved shipped category counted as zero at full weight, splits it into score effects of categories present in both releases and a composition effect from categories that enter or leave. Composition accounts for 25 percent of the summed absolute change in ES and 40 percent in EO. When the entering or leaving category is constant within a cell (the zero Investment cells, Energy Prices, readiness) it moves the cell's level and leaves the ordering unchanged; the reorderings come from rebuilt inputs, chiefly Foreign Dependency in the ES Upstream, Trade in the ES Midstream and Consumption or Investment in the ES Downstream. The extreme case is EO Green Hydrogen Midstream, with a within-cell correlation of −0.55: both releases rank its economies mostly on imputed values, and neither ranking should be read as a measurement. ES Nuclear Midstream combines the largest level shift (a mean gain of 0.24, from the removal of the zero Investment category) with a within-cell correlation of 0.59 (from the rebuilt Trade category).

Coalition members. Among the 57 members the rankable matched cells number 1,468 (ES) and 1,716 (EO), with correlations of 0.82 and 0.68, close to the full sample. Figure 47 and Table 34 show the twelve largest changes in each pillar, at most two per cell. The largest are Canada and Namibia in Nuclear Upstream, from zero to 0.74 and 0.72 in ES: the shipped cell held only the zero Investment category, and the Red Book places both among the leading holders and producers of uranium. The others trace the rebuilt themes: consumption (E5), the zero-filled Investment cells (E7), the new Upstream trade baskets, mirror trade for Gabon, which did not report imports in 2024, and the reviewed copper and aluminium basket for the United States in Electric Grid Upstream. Eight of the twelve ES changes and seven of the twelve EO changes are mainly composition effects, so they matter most for comparisons across one country's cells, which is what the Strategic Index makes.

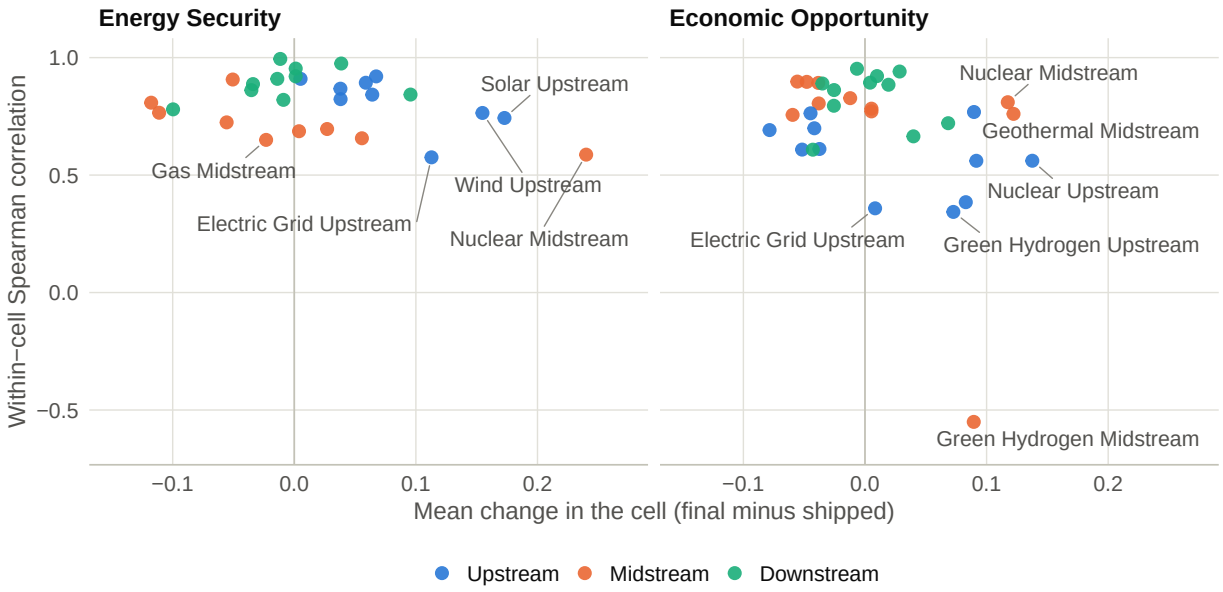

Figure 46: Level shift and rank agreement by technology–stage cell. Each point is one cell. Horizontal axis: mean change of the pillar (final minus shipped) across the economies scored in the cell in both releases and rankable in the final release. Vertical axis: Spearman correlation of the shipped and final values across the same economies. Colour marks the stage; labels name the three cells with the lowest correlation and the three with the largest absolute mean change in each panel. Energy Security: 28 cells (Nuclear Upstream, constant in the shipped release, is excluded; Geothermal Upstream and Midstream and Electric Grid Downstream have no final score; Green Hydrogen Midstream had no shipped one); Economic Opportunity: all 33 cells. A point far from zero horizontally but high vertically is a level shift that left the ordering largely intact. Sources: as in Figure 45.

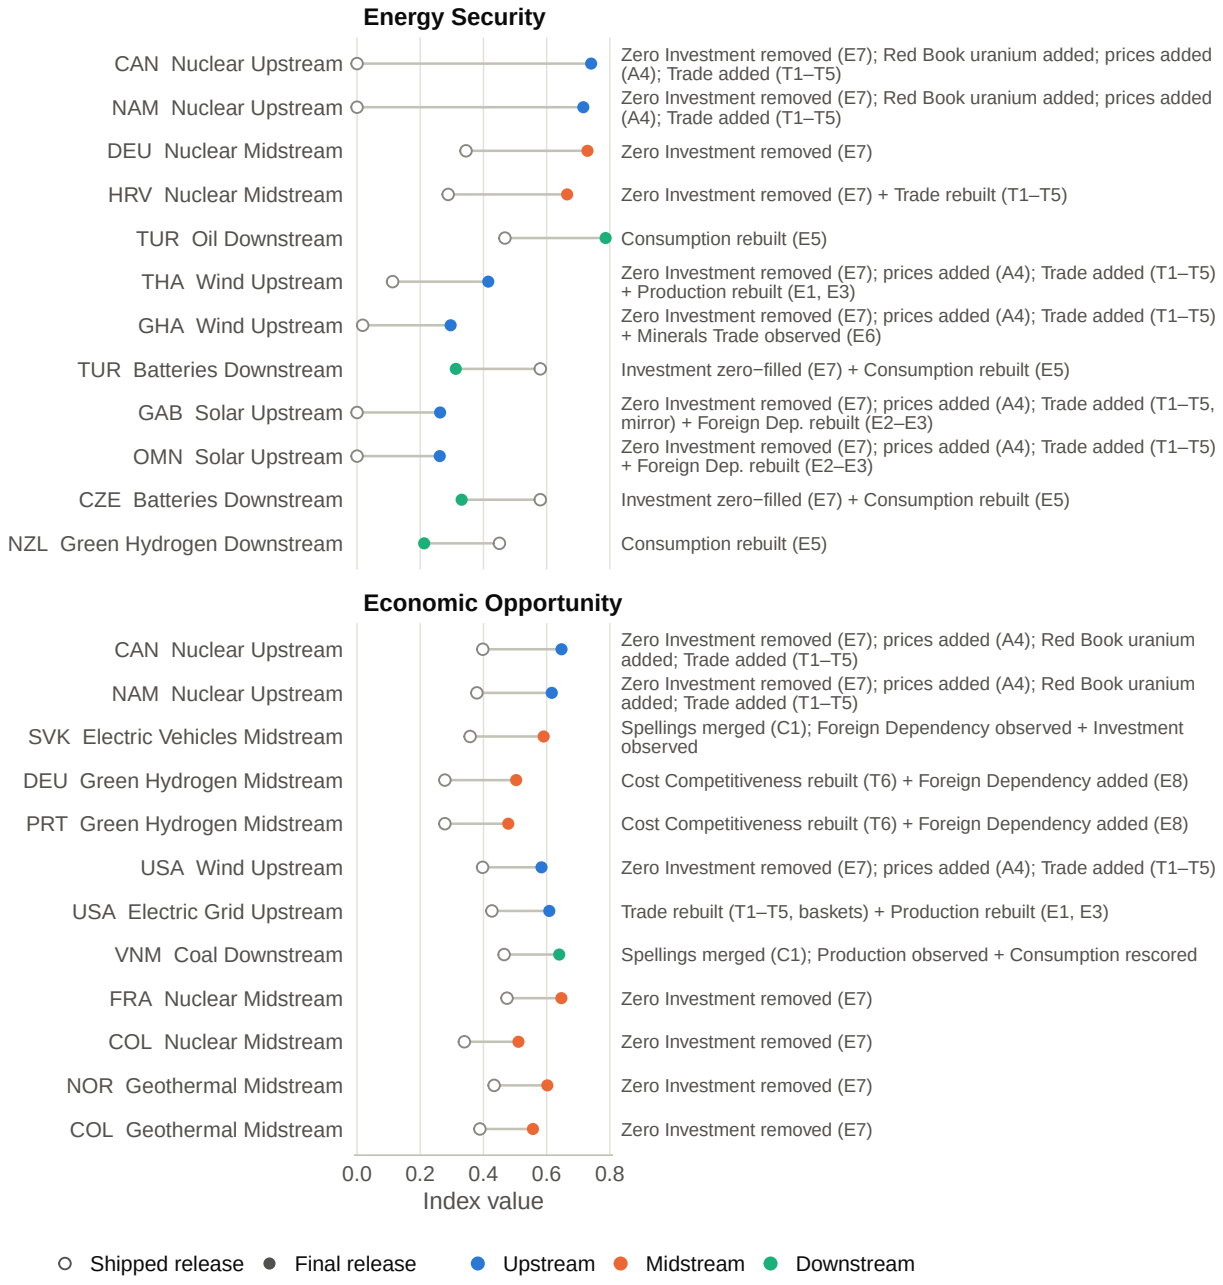

Figure 47: The twelve largest changes among coalition members, by pillar, at most two per technology–stage cell. Each row is one member's cell (ISO3 code). Hollow circles mark the shipped value and filled circles the final value, coloured by stage. The text at the right names the cause: the largest effect in a two-factor Shapley decomposition of the change into category score effects and a composition effect (categories entering or leaving and the renormalisation of weights), and the second when it is at least half as large, with the data change behind it ("Red Book uranium": OECD-NEA/IAEA resources and production; "mirror": trade measured from partners' declarations). Item codes refer to Table 31; the full decomposition is in Table 34. Sample: the 57 members of the final coalition, cells present in both releases and rankable in the final release (Energy Security in Nuclear Upstream, constant in the shipped release, is included as a mover). Sources: `category_contributions` of the two `index_outputs.rds`.

Notes: The 12 largest absolute changes, final minus shipped release, of ES_{its} and of EO_{its} among the 57 members of the final coalition, at most 2 per technology–stage cell, over the headline cells present in both releases that the final release ranks (sovereign economy, at most half of the index weight imputed); cells that were constant across countries in the shipped release are included. The change is split by a two-factor Shapley decomposition of the weighted category mean: the score effect of a category present in both releases is $\frac{1}{2}(\omega_k^{\text{shipped}} + \omega_k^{\text{final}})(c_k^{\text{final}} - c_k^{\text{shipped}})$, with ω_k the normalised category weight and an unobserved shipped category counted as $c_k = 0$ (item A1); the composition effect is the remainder, due to categories that enter or leave and to the renormalisation of the weights. The cause names the largest effect, and the second when it is at least half as large; item codes refer to Table 31. Data changes: "uranium, Red Book" = identified recoverable resources and mine production of the OECD-NEA/IAEA Red Book; "USGS MCS 2026" = critical-mineral reserves of the USGS Mineral Commodity Summaries 2026; "all-reporter dyads" = trade rebuilt from all-reporter Comtrade dyads (importer report first, else the exporter's declaration ×1.06) and the energy-trade file rebuilt from the same pull; "basket review" = a stage whose HS6 basket the October 2026 review changed; "mirror imports" = an economy that did not report 2024 imports, whose imports come from partners' declarations; "TRL by stage" = technology readiness mapped by stage from the IEA Clean Technology Guide. Source: `category_contributions` of the two `index_outputs.rds`.

Strategic Index. The shipped index scored 571 cells of 18 economies of its hand-picked list; the final one scores 3,154 cells of 174 countries in 30 sectors. On the 477 cells scored in both the correlation is 0.74, and across sectors within a country the median is 0.74 (Argentina 0.42 to Kenya 0.92). The policy term changed most. The shipped Policy index combined IEA PAMS, CAT, the February 2026 NIPO component and the dual-use score; the final one combines IEA PAMS and CAT, and all 18 economies have both. The within-country policy term correlates only 0.61 between releases and accounts for 40 percent of the summed absolute change, against 35 percent for security need, 22 percent for EO and 3 percent for the fixed weights, which differ only through the technology weights of oil (0.12 shipped, 0 final) and coal (0 and 0.02; item P9). In the final run 215 countries are policy-eligible (65 on IEA PAMS and CAT, 150 on IEA PAMS alone); all 23 economies of the shipped hand-picked list are among them, as are all 57 members of the derived coalition. Figure 48 splits the twelve largest changes into their terms. For the final release Geothermal Midstream is excluded by rule, as before; no sector is constant in either pillar, because Nuclear Upstream now varies with the Red Book data; and Electric Grid Downstream and Geothermal Upstream have no ES value, so the index covers 30 sectors.

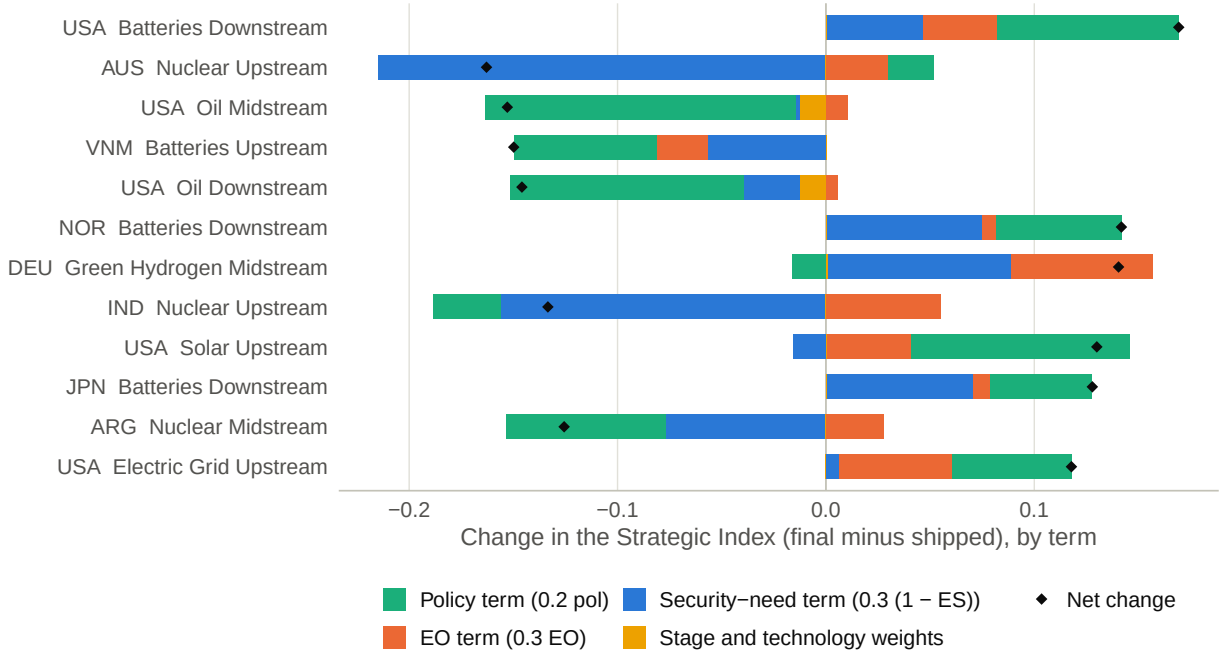

Figure 48: The twelve largest changes in the Strategic Index among the economies scored in both releases, split into the weighted terms of $\mathrm{SI} = 0.2\,\mathrm{POL} + 0.3\,\mathrm{EO} + 0.3\,(1 - \mathrm{ES}) + 0.1\,\lambda_s + 0.1\,g_t$. Each bar is one country–sector cell; the segments are the changes of the policy term, the EO term, the security-need term and the two fixed weights combined, and the diamond is the net change, which the segments sum to exactly. The shipped policy term is the within-country S-curve of the four-component Policy index of February 2026 (IEA PAMS, CAT, NIPO, dual use); the final one is that of IEA PAMS and CAT. The policy term is the largest contributor in seven of the twelve, security need in five. Sample: the 477 cells of the 18 economies of the shipped hand-picked list scored in both releases. Sources: `strategic_index` of the two `index_outputs.rds`; `scripts/paper/fig_reconcile.R`.

The allied picks. The shipped picks were made over a hand-picked list of 23 economies, the final ones over the 57 members of the derived coalition, so the comparison covers the 21 they share (Table 35). Kenya and the United Arab Emirates are not members of the final coalition, and Denmark, France, Italy and South Korea had no shipped pick because they lacked a Policy index (P3). Of the 17 members with a pick in both releases, 16 change it; only Chile keeps Nuclear Upstream. Six changes (Australia, Brazil, Canada, India, Mexico and the United States) are reorderings by the security-need term: all six picked Nuclear Upstream where the shipped ES was zero for everyone, and the Red Book now records uranium for all six. Four (Argentina, Indonesia, South Africa, Viet Nam) are reorderings by the policy term, four (Germany, Japan, Morocco, Norway) are barred by the endowment screen, and two (Saudi Arabia, the United Kingdom) are no longer scored because the EO cell of the shipped pick is not rankable. On these members the picks move from Nuclear Upstream (8) and Batteries Upstream (5) to Batteries Midstream (13).

Partnership strength. The shipped release did not write the PSI to disk; reconstructed from the March 2026 partner tables with the shipped logic, it correlates -0.09 with the final world view over 187 partners and -0.33 with the core view over 191. The denominator defect (B4) placed high-income partners below the others, so correcting it moves that group up as a block: the United States moves from 168th to 4th of the 187 in the world view and to 1st in the core view, and Germany from 135th to 5th. China moves from 22nd to 1st in the world view but to 44th in the core view, whose Friendshore scores rate China from the core members' viewpoints, alignment included.

Using numbers from the shipped release. Within a technology–stage cell, shipped pillar rankings are a rough guide in the Downstream (median within-cell correlations 0.90 for ES and 0.88 for EO) and in the EO Midstream (0.80), a poor guide in the ES Midstream (0.70) and the EO Upstream (0.61), and no guide for EO Green Hydrogen Midstream. Comparisons across cells, and with them the shipped Strategic Index and its picks, inherit the level shifts and a different Policy index; the shipped picks should be replaced by those of Section 9. Any PSI computed from the shipped partner tables should not be used, nor the shipped network outputs. As the composite-indicator literature warns, the ordering a composite produces can depend on its construction as much as on its data (Saisana et al., 2005; Saltelli, 2007); here, however, the large changes come from defects and new data rather than from defensible alternative choices, so they are corrections, not a measure of uncertainty.

Table 35: Allied pick per member of the shipped list: shipped and final release

	Shipped release		Final release		
Member	Pick	SI	Pick	SI	Status or cause of change
Argentina	Electric Vehicles, Midstream	0.624	Batteries, Upstream	0.551	reordered by the policy term
Australia	Nuclear, Upstream	0.656	Batteries, Midstream	0.610	reordered by the security-need term
Brazil	Nuclear, Upstream	0.613	Batteries, Midstream	0.606	reordered by the security-need term
Canada	Nuclear, Upstream	0.638	Electric Grid, Midstream	0.615	reordered by the security-need term
Chile	Nuclear, Upstream	0.626	Nuclear, Upstream	0.645	unchanged
Denmark	–	–	Batteries, Midstream	0.636	new
France	–	–	Batteries, Midstream	0.642	new
Germany	Batteries, Upstream	0.712	Batteries, Midstream	0.623	shipped pick screened: no resource base
India	Nuclear, Upstream	0.643	Batteries, Midstream	0.628	reordered by the security-need term
Indonesia	Electric Vehicles, Midstream	0.642	Nuclear, Midstream	0.568	reordered by the policy term
Italy	–	–	Batteries, Midstream	0.639	new
Japan	Batteries, Upstream	0.657	Nuclear, Upstream	0.620	shipped pick screened: no resource base
Kenya	Batteries, Upstream	0.701	*not a member*	–	not in final coalition
Mexico	Nuclear, Upstream	0.624	Batteries, Midstream	0.564	reordered by the security-need term
Morocco	Solar, Upstream	0.683	Electric Grid, Midstream	0.609	shipped pick screened: no resource base
Norway	Nuclear, Upstream	0.729	Batteries, Upstream	0.618	shipped pick screened: no resource base
Saudi Arabia	Batteries, Upstream	0.688	Nuclear, Upstream	0.567	shipped pick not scored: EO not rankable
South Africa	Electric Grid, Midstream	0.679	Batteries, Midstream	0.620	reordered by the policy term
South Korea	–	–	Batteries, Midstream	0.635	new
United Arab Emirates	–	–	*not a member*	–	not in final coalition
United Kingdom	Batteries, Upstream	0.690	Batteries, Midstream	0.617	shipped pick not scored: EO not rankable
United States	Nuclear, Upstream	0.613	Batteries, Midstream	0.632	reordered by the security-need term
Viet Nam	Batteries, Upstream	0.698	Batteries, Midstream	0.606	reordered by the policy term

Notes: The pick is the member's Upstream or Midstream sector with the highest Strategic Index; Geothermal and Green Hydrogen are excluded by rule of the selection. Shipped release: the Strategic Index of 3 September 2026 over its hand-picked list of 23 economies, of which 18 had a pick. Final release: `data/processed/charts/allied_strategic.csv`, over the derived coalition of 57 members, with the endowment screen (an Upstream extraction stage is eligible only where the member has recorded reserves or production of its resources). The comparison is on the 21 members the two lists share; 2 economies of the shipped list are not in the final coalition. "new": a pick only in the final release. Cause of a change: the shipped pick is no longer scored (its exclusion), is barred by the endowment screen, or is outscored, in which case the term of the index that contributes most to the reversal of the two sectors' order is named (an exact split of the reversal into the five weighted terms). The picks of the other 36 final members are reported in Section 9.

Online Appendix

Opportunity, Security, and the Allied Industrial Base

Further detail, derivations and diagnostics

OA.1 Data: releases, harmonisation and years

The release rule. Inputs that are published in successive releases are staged under a file-name pattern, and the run selects one release by rule rather than by hand. Let F_P be the staged files matching the pattern of input P, $k(f)$ the vintage key parsed from a file's name (a date or a year), $m(f)$ its modification time and $R(f)$ the number of distinct reporters in a tabular extract. The release used is

$$f_P^* = \operatorname*{lex\,max}_{f \in F_P:\ R(f) \geq \underline{R}_P} \big(k(f),\, m(f)\big), \tag{OA.1}$$

the newest declared vintage, with the modification time breaking ties and ordering unversioned names, among the files that meet the coverage floor $\underline{R}_P$. The floor is 50 reporters for the Comtrade critical-minerals extracts and absent elsewhere. Comtrade publishes a year's data as reporters file, so the newest file can be a stub: the 2025 critical-minerals extracts have three reporters each and are skipped in favour of the 2024 extracts (130 import, 128 export and 130 total-export reporters). Every run writes the releases it resolved, with their reporter counts, to a vintage stamp (`data/raw/raw_inputs_resolved.yml`); Appendix B reports them. Inputs that are not pattern-resolved (the Comtrade dyads, the Red Book and USGS tables, the EIA bulk file, CM-FDI, the ideal points and the project-authored lists) are single staged files whose access dates are recorded in the input manifest.

Harmonisation of economies. Every source is put on one canonical name per economy before anything is ranked: the World Development Indicators name of the economy's ISO3 code, matched through the `countrycode` package and a curated table of spellings. Taiwan, which the World Bank's country table does not list, is added under its own code, including to the rosters of the trade themes; Kosovo is carried as XKX. World, regional, income-group and residual rows ("Other Asia Pacific", "Rest of world") and historical entities are dropped from every theme table, so that no aggregate is imputed or averaged as if it were an economy; theme builders also remove aggregates from their comparison sets before ranking, while keeping them in world denominators where the source defines the world total. Keys that two spellings of one economy share are collapsed, with a warning if both carry different non-missing values. Sovereignty, which the rankability rule uses, follows the Correlates of War state-system list (Correlates of War Project, 2024): 195 states in 2024, the 193 UN members plus Kosovo and Taiwan.

Fossil production from EIA. The Statistical Review lists fewer producers than consumers and counts the rest in regional "Other" residuals. Where it has no production row for an economy and fuel, the value is taken from the EIA International Energy Statistics (U.S. Energy Information Administration, 2026) (bulk file of 3 October 2026) in the Review's units: oil as crude oil including lease condensate plus natural-gas plant liquids, in thousand barrels a day; gas as dry gas in billion cubic metres times 0.036 EJ; coal as terajoules (gross calorific value) times 0.95×10^{-6} EJ. On economies both sources report, the median ratio of the Review's value to the converted EIA value is 1.006 to 1.011 for oil, 0.97 to 0.99 for gas and 0.99 to 1.05 for coal. An EIA value is not used when EIA's consumption of the fuel covers less than a tenth of the Review's, since the Review then counts under the fuel something EIA excludes; in 2015–2025 this affects only Estonian coal (oil shale), which stays missing. Where EIA's latest production year precedes the Review's consumption year (2025 gas and coal from EIA 2024), self-sufficiency is computed with consumption of the same year and carried forward. EIA values are observations, not imputations.

Reserves and uranium. The USGS Mineral Commodity Summaries 2026 data release (U.S. Geological Survey, 2026) gives country reserves at end-2025; the report's version 1.3 erratum puts Brazil's rare-earth reserves at 11 Mt (the Statistical Review's mineral sheet, an older USGS copy, gives 21 Mt). A reported zero scores 0; a holder listed without a figure (NA, W or s) is missing in its mineral variable, scored 0 and counted as imputed, and counts as zero in the technology roll-ups, so world shares are measured on quantified holdings. "Other countries" and world-total rows are never holders. The Red Book (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026) supplies identified recoverable resources (reasonably assured plus inferred) below USD 260/kgU at 1 January 2025 (Table 1.2a of *Uranium 2026*) and mine production (Table 1.18; *Uranium 2026* for 2022–2024, earlier editions for 2019–2021), completed with observed zeros over the economies of the Statistical Review and the World Development Indicators.

Bilateral trade. The all-reporter dyad file was pulled on 7–8 October 2026 for the pre-review product list, with supplements on 9 October (the copper and aluminium inputs of the grid) and 12 October (the new upstream codes). Comtrade's partner S19 ("Other Asia, n.e.s.") is mapped to Taiwan. Liberia, Mali and São Tomé and Príncipe filed 2024 data after the pull and enter through their partners' declarations. The country-level energy-trade file is derived from the pull's World rows; an earlier direct extract, with 129–130 reporters, lacked 60 basket codes and Qatar's exports of liquefied natural gas. Critical-minerals exports of non-reporting economies are measured from partners' imports, moved from CIF to FOB with an HS-chapter ratio estimated on importers that file both values.

Regional and staged inputs. The IEA's 2035 announced manufacturing-capacity shares and its electric-vehicle production and sales are regional for Europe, so EU members carry the EU's value; economies outside the IEA's named regions take its "Rest of world" values. ILOSTAT earnings are read from a copy staged on 30 September 2026, since the ILO's interface returns empty responses

Table OA.1: Years of the inputs in the final run

Source	Years used
EI Statistical Review 2026	Consumption and production to 2025 (growth 2020–2025); fossil reserves end-2020
EIA International Energy Statistics	Oil production to 2025; gas and coal to 2024
USGS Mineral Commodity Summaries 2026	Reserves end-2025
Red Book (Uranium 2026)	Resources at 1 January 2025; production 2019–2024

Notes: Each component enters at the latest year its source reports (equation (13)). Appendix B gives the releases.

to scripted requests. In the IMF lending-rate series a zero reading in a lending-type rate is a placeholder and is dropped with the averages that include it: New Zealand's lending series carries only zeros after January 2017, so its last genuine reading (4.76 percent) is used. Commodity prices are in the units of the IMF series metadata.

Index vintages. The headline indices are a single snapshot. A separate build re-cuts each raw input to a requested year and reruns the same theme and pillar builders, so that the pillars can be compared across years (Section 12). Only sources with a genuine time dimension move: the Statistical Review, the Atlas trade data, IMF prices and rates, ILOSTAT earnings and Clean Investment Monitor investment. Resource potential, reserves, the IEA critical minerals release, BloombergNEF demand and costs, overcapacity and technology readiness are snapshots or projections and are held fixed; a 2025 vintage uses Atlas 2023. The build records, for each vintage, the share of each pillar's scored weight that re-derives and the year to which each source resolved.

Algorithm OA.1 Construction of a pillar index $P \in \{\mathrm{ES}, \mathrm{EO}\}$ from its theme tables

Require: theme tables $h \in \mathcal{H}_P$; category weights w_k (`config/weights.yml`); missing-data rules $m_h \in \{\text{zero}, \text{global average}\}$ (`config/missing_data.yml`); for each category its score variable and components $\mathcal{V}_k$ (`config/index_definition.yml`)

Bind the theme tables; average rows that differ only by sub-sector; keep rows whose data type is *index*
For each (i, t, s, k, v, h) keep the observation with the latest year ▷ eq. (13)
for each technology–stage pair (t, s) **do**
    Complete the grid of economies × component groups
    for each group $g = (t, s, k, v, h)$ **do**
        if at least one economy is observed in g and theme h has a rule **then**
            Fill the missing economies of g by rule m_h from the observed values ▷ eq. (14)
        end if
    end for
end for
Average each component over themes; score each category by the mean of its present components ▷ eq. (15)
Aggregate the observed categories of each cell with renormalised weights ▷ eq. (16)
Record category and variable contributions, ι_{its} and the pair status; flag rankable cells ▷ eqs. (19)–(22)

Ensure: $P_{its} \in [0, 1]$, or missing when no category of the cell is observed

OA.2 Index construction: derivations and further diagnostics

This appendix collects the construction algorithm, the properties of the S-curve that Section 4 uses without proof, the conventions of the theme and aggregation layers, and the diagnostics of the final build that the main text summarises.

Theme tables and orientation. Every theme table has one row per economy, technology, stage, sub-sector, category, variable, data type and year, with its value, source and a short explanation. Rows of type *raw* keep a metric in natural units for tracing; only rows of type *index*, on $[0, 1]$, enter the pillars. Rows that differ only by sub-sector are averaged with equal weights before any other step. Each variable is oriented in its theme: concentration enters through $-$HHI, a trade deficit relative to GDP, a levelised cost and price volatility through their negatives. By the symmetry of ϕ_γ, the S-curve of $-x$ is one minus the S-curve of x for any comparison set with at least two observations, so orientation and transformation commute. The opportunity builder verifies that every category score lies in $[0, 1]$.

The S-curve. Differentiating equation (10),

$$\phi'_\gamma(r) = \frac{\gamma\,[r(1-r)]^{\gamma-1}}{\left[r^\gamma + (1-r)^\gamma\right]^2}, \qquad \phi'_\gamma(1/2) = \gamma, \tag{OA.2}$$

which for $\gamma < 1$ diverges as $r \to 0$ or $r \to 1$. With $\gamma = 0.5$ the quartiles map to 0.366 and 0.634, so near the median a step in rank moves the index by half as much as it moves the percent rank, while gaps between adjacent units are widened in the tails. In levels, $\phi_\gamma(r) > r$ below the median and $\phi_\gamma(r) < r$ above it. With n untied observations the index takes exactly the values $\phi_\gamma(k/(n-1))$, $k = 0, \ldots, n-1$, whatever the raw distribution, so every untied S-curved variable has mean $1/2$ and a dispersion that depends only on n and γ: the population standard deviation is 0.260 for $n = 10$, 0.224 for $n = 20$ and 0.206 for $n = 40$, and tends to 0.19, against 0.29 for the percent rank and 0.38 for $\gamma = 2$. Components ranked over comparison sets of a given size therefore enter a category on a common scale; smaller sets have larger spreads, and ties, the zero anchor and imputed values move a component away from the grid. The smallest step above zero, $\phi_\gamma(1/(n-1))$, is coarse in small sets (0.261 for $n = 10$, 0.140 for $n = 40$). A single observation scores 0, two score 0 and 1, and a fully tied set scores $1/2$. In the simulated lognormal sample of Figure 4, min-max rescaling puts 29 of 40 observations below 0.1 and spreads the top four over 0.79 of the scale; the percent rank gives each group of four a spread of 0.077; the S-curve gives the bottom and top four 0.22 each and the middle four 0.04. Rank-based normalisation is a standard option for composite indicators (Nardo et al., 2008); it is adopted because the inputs differ in units and skewness by orders of magnitude and the questions the indices answer are comparative. Min-max or z-score normalisation would let a few very large values compress the rest of the distribution.

The zero anchor. Equation (12) is equation (10) applied to the positive values with a single zero prepended to the comparison set and then removed. An observed zero and an unrecorded economy both score 0, and the smallest positive value scores $\phi_\gamma(1/m) > 0$: for $(0, 2, 5, 9)$ the positive entries score 0.414, 0.586 and 1. A set in which every value is zero scores 0 throughout.

Comparison sets and cardinal exceptions. Most themes rank the economies observed in a pair, sometimes split by sub-sector, year or mineral before averaging to the pair. World-level series are ranked across the units over which they vary: commodity-price volatility across technologies, world export concentration across the cells of the eleven headline technologies, and global demand across fuels. A theme that builds a composite of several S-curved terms averages them and may pass the average through the S-curve again. Index values are positions in a cross-section: adding or removing economies changes the scores of the others, and a change over time records a change in standing against the field. The three cardinal EO inputs are the readiness score (a raised-cosine bell in the readiness level, zero at levels 2 and 11 and peaking at 6, blended 0.7:0.3 with a capped concave score of its recent increase), the overcapacity term $2^{-\rho}$ in BloombergNEF's ratio ρ of capacity to forecast demand, and the capital-cost term of the input-cost index, a lending rate winsorised at its 5th and 95th cross-country percentiles and rescaled by min-max. They keep interval information and do not share the fixed distribution of an S-curved variable; the first two are technology-level values.

Latest year. The selection of equation (13) is made on the year field, with undated rows at year 0, separately for each economy and variable. A row recorded for a later year with a missing value therefore supersedes an earlier observed value. In ES the mixed years lie between 2023 and 2025, apart from the 2035 horizon of the announced manufacturing-capacity shares. In EO part of the mixing reflects the projection horizons of the outlook series; counting only years up to 2026, 91 percent of EO cells still combine more than one vintage, with at most four years and a median spread of three among the cells that mix. The extreme case is the input-cost index of Papua New Guinea, whose latest observation is for 1980 and which enters all 33 of its EO cells through Cost Competitiveness.

The grid and the rules. Because a pair's grid is the union of the economies of all the pillar's themes for the pair, one broadly distributed theme sets its extent: the commodity-price series is copied to every economy of the World Bank list at the upstream stage, so every such economy enters the upstream grid of each technology with a price series and is scored there on its other components, observed or filled. Rows of categories a pillar does not score cannot add economies to its grid. Every one of the 219 economies in the upstream grids has a country-specific upstream component in at least one upstream pair of each pillar. When a single economy is observed in a group, the global-average rule copies its value to every other economy: this is how the Boston Consulting Group estimate of the U.S. serviceable addressable market, one value per pair, enters EO Technology Demand, flagged as imputed for every economy but the United States. Because the average is taken after the latest-year selection, it can combine observations of different years. The zero rule equates "not recorded" with "none" and so understates the position of an economy an incomplete register omits.

Overall variables. A component reported by several themes (energy consumption per capita, for example) is averaged across them with equal weights before the category mean. Some component lists follow a one-vote-per-source principle: where a source enters through a composite of its own terms, the composite is one component. Two checks guard the mapping from configuration to data: the builder warns when none of a category's listed components occurs in the inputs, and it discards any theme row that carries the name of a configured overall variable, so the configured definition always governs. A configuration test requires the weighted categories of each pillar to coincide with its configured categories.

Why not zero-fill. Replacing each unobserved category by the cell's available-case mean and averaging over all categories with the nominal weights returns ES_{its} unchanged. Scoring an unobserved category as zero while keeping its weight in the denominator gives instead

$$\mathrm{ES}^{\mathrm{zero}}_{its} = \mathrm{ES}_{its} \cdot \frac{\sum_{k \in K_{its}} w_k}{\sum_{k \in \mathcal{K}^P} w_k}, \tag{OA.3}$$

which multiplies the index by the observed share of the nominal weight. An earlier version of the code behaved in this way for categories present as rows but unobserved; Appendix D documents the correction. Since no cell observes all ten categories, listwise deletion at the category level would leave every cell unscored.

Category sets. Figure OA.1 shows the categories that enter each pillar in each headline pair. The 30 ES pairs use 16 distinct category sets and the 33 EO pairs 18; no pair observes all ten categories of either pillar. The variation is structural: only Trade, Foreign Dependency and Investment exist at the midstream stage of ES, and only Consumption, Energy Access, Investment and, for the three renewables with a resource-potential series, Reserves downstream. In seven ES pairs the pillar is a single category (Trade in the coal, gas, nuclear and oil midstream pairs; Foreign Dependency in Green Hydrogen midstream; Investment in Electric Vehicles downstream; Consumption in Green Hydrogen downstream). Nuclear upstream is scored on Production, Reserves, Trade and Energy Prices; its Trade category, like those of the Electric Vehicles, Solar and Wind upstream pairs in both pillars, comes from the new upstream baskets. The narrowest EO pair, Electric Grid downstream, has only Cost Competitiveness and Technological Readiness. Energy Prices is constant within the ten upstream pairs with a price series, Technological Readiness within all 33 EO pairs, and Technology Demand within five EO pairs (Batteries upstream and midstream, Geothermal at all three stages).

Effective weights and constant inputs. Averaging effective weights over cells instead of pairs changes the stage means by at most 0.032, because the category set is common within a pair; the largest gap between effective and nominal share is 0.49. Upstream ES weight is spread more evenly, led by Reserves (0.20), Trade (0.18) and Production (0.18); Energy Prices, nominally 0.048, carries 0.10. In EO the redistribution favours categories observed at every stage: Technology Demand (0.20 to 0.25, nominal 0.133), Cost Competitiveness (0.19 to 0.24, nominal 0.100) and Technological Readiness (0.12 to 0.16, nominal 0.067). Categories constant within the pair take a mean of 0.34 of the weight of an upstream EO cell, 0.22 at the midstream stage and 0.18 downstream; adding the constant components inside varying categories (world export concentration in Trade; the addressable-market, global-demand and overcapacity terms of Technology Demand) raises these shares to 0.46, 0.39 and 0.27. The corresponding component-level shares in ES are 0.16, 0.20 and 0, the midstream figure being the world export-concentration term of Trade. Energy Prices is copied to every economy before ranking, so the economies of a technology form one block of tied ranks: with T technologies the technology in position p receives a percent rank close to $(p - \frac{1}{2})/T$ rather than $(p-1)/(T-1)$, and no technology scores exactly 0 or 1.

Imputation burden by category. Table OA.2 gives the values behind Figure 6. Upstream, Reserves (0.84) alone accounts for 0.17 of the ES stage mean of 0.41; Energy Imports (0.55), Foreign Dependency (0.50) and Production (0.43) also cover only part of the grid, and the upstream Trade category is imputed at 0.19. In EO, Technology Demand is imputed at 0.73 to 0.86 and contributes

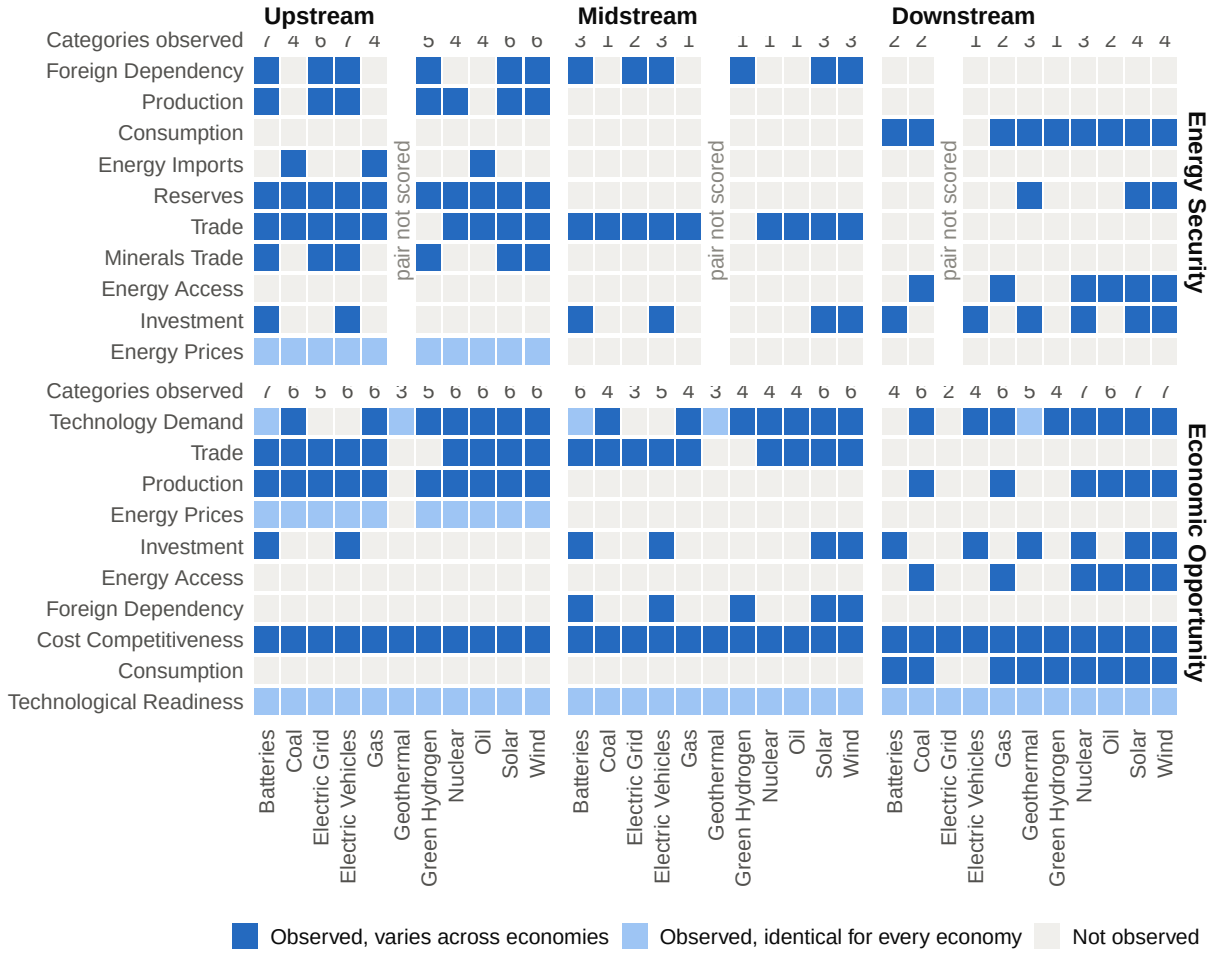

Figure OA.1: Category composition of the pillars by technology–stage pair. Each column is one of the 33 headline technology–stage pairs, grouped by stage. Each row is a category of the Energy Security pillar (upper block) or the Economic Opportunity pillar (lower block), ordered by nominal weight as in Table 7. Dark blue: the category is observed in the pair and its score varies across economies. Light blue: the category is observed but takes the same score for every economy of the pair (a world- or technology-level input). Gray: the category is not observed in the pair. The number above each column is the number of observed categories, which is the same for every economy of the pair. "Pair not scored" marks the three pairs without an ES value. Sample: the country–technology–stage cells of the eleven headline technologies that have a pillar value (6,232 for ES, 7,131 for EO). Source: category contributions in `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_method.R`.

Table OA.2: Mean imputed share by category, stage and pillar, headline technologies

	Energy Security			Economic Opportunity		
Category	Up	Mid	Down	Up	Mid	Down
Consumption	–	–	0.03	–	–	0.05
Cost Competitiveness	n.a.	n.a.	n.a.	0.34	0.42	0.36
Energy Access	–	–	0.65	–	–	0.66
Energy Imports	0.55	–	–	n.a.	n.a.	n.a.
Energy Prices	0.01	–	–	0.01	–	–
Foreign Dependency	0.50	0.54	–	–	0.79	–
Investment	0.83	0.78	0.64	0.83	0.78	0.66
Minerals Trade	0.02	–	–	n.a.	n.a.	n.a.
Production	0.43	–	–	0.68	–	0.55
Reserves	0.84	–	0.10	n.a.	n.a.	n.a.
Technological Readiness	n.a.	n.a.	n.a.	0.04	0.02	0.03
Technology Demand	n.a.	n.a.	n.a.	0.86	0.73	0.83
Trade	0.19	0.01	–	0.26	0.15	–
Pillar, $\bar{\iota}$	0.41	0.23	0.27	0.41	0.44	0.43
Cells	2,181	2,002	2,049	2,394	2,346	2,391

Notes: Category rows give the mean, over the country-technology-stage cells of the eleven headline technologies in which the category is observed, of the share of the category score carried by imputed components, $\sum_v \lambda_{vkits} \mathbf{1}[\tilde{x}_{itsv}$ imputed$]$. The pillar row gives the mean over all scored cells of the stage of the imputed weight share ι_{its} of equation (21). –: category not observed at that stage; n.a.: category not part of the pillar. Source: `data/processed/outputs/index_outputs.rds` (variable contributions and the pillar diagnostics); `scripts/paper/fig_method.R`.

0.16 to 0.19 to each stage mean: the addressable-market term counts as imputed for every economy but the United States, the regional outlook is observed for a median of 12 economies per pair, and the world-level global-demand series is recorded for 108 economies and filled with the same value for the rest. Investment is imputed at 0.64 to 0.83 in both pillars. World-level series show almost no imputation (Energy Prices below 0.01, Technological Readiness at most 0.04), which is why ι_{its} records how a value was obtained rather than whether it is country-specific, and why the rankability rule can admit a cell whose observed weight is largely world-level. A component averaged across two themes counts as imputed if either value was, so ι_{its} is an upper bound there. At the other extreme, 2,055 ES cells (33 percent) and 407 EO cells (6 percent) contain no imputed component. Rebuilding ι_{its} from the variable table reproduces the builders' value to within 1.1×10^{-16}.

Mass points and pair status. Economies without country-specific data share one value within their pair: in five EO pairs (Electric Grid downstream, Green Hydrogen upstream and midstream, Geothermal upstream and midstream) 65 to 70 economies sit at a single interior value, and none of these cells is rankable. Observed zeros create mass points that the rule does not remove: in ES, 98 of the 109 economies scored in Green Hydrogen midstream share the pair's minimum (0.256), 95 of them rankable, and in Nuclear upstream 127 of 218 share one value (0.172), 105 of them rankable. Such a tie records a real absence of production or resources but becomes a uniform, sector-wide

Table OA.3: Rankable cells by pillar and stage, headline technologies

	Scored cells	Rankable cells	Not rankable		Share rankable	Economies ranked
			Territory	$\iota_{its} > 0.5$		
Energy Security						
Upstream	2,181	1,124	231	826	0.52	195
Midstream	2,002	1,397	169	436	0.70	192
Downstream	2,049	1,642	207	200	0.80	193
All stages	6,232	4,163	607	1,462	0.67	195
Economic Opportunity						
Upstream	2,394	1,681	250	463	0.70	178
Midstream	2,346	1,307	221	818	0.56	166
Downstream	2,391	1,313	247	831	0.55	169
All stages	7,131	4,301	718	2,112	0.60	178

Notes: Country–technology–stage cells of the eleven headline technologies with a pillar value. A cell is rankable when the economy is a sovereign state (a Correlates of War state-system code) and at most $\tau = 0.5$ of its index weight rests on imputed components, $\iota_{its} \leq \tau$ (`config/rankability.yml`). Reasons are exclusive: a territory is counted as a territory whatever its imputed share; the next column counts sovereign cells over the threshold. Economies ranked: economies with at least one rankable cell. Source: `data/processed/outputs/index_outputs.rds`; `scripts/paper/fig_method.R`.

need under the security-need reading of the Strategic Index. A pair is *unscored* if no economy has an observed category, *constant* if at least two are scored and their range is at most 10^{-12}, and *ok* otherwise. Over every technology, including those outside the headline set, all 45 ES pairs and all 40 EO pairs are ok; Nuclear upstream, constant before the uranium data were added, now varies. Electric Grid downstream and Geothermal upstream and midstream have no observed ES category.

Rankability in detail. Table OA.3 gives the counts behind Figure 7. Counted over sovereign cells only, the rule keeps 74 percent of ES and 67 percent of EO cells. Rankable sovereign cells score higher on average than sovereign cells over the threshold in every pillar and stage, most markedly in midstream ES (0.46 against 0.30) and midstream EO (0.49 against 0.37). The narrowest pairs keep a usable comparison set: Green Hydrogen midstream keeps 40 rankable EO cells (19 percent of those scored), and Nuclear downstream, the narrowest ES pair, keeps 68. The 17 sovereign states without a rankable EO cell are Liechtenstein, Monaco, Djibouti, Dominica, Eritrea, Haiti, Kiribati, the Marshall Islands, Micronesia, Nauru, North Korea, Palau, São Tomé and Príncipe, Somalia, St Kitts and Nevis, St Vincent and the Grenadines and Tuvalu; their only rankable EO cells had been upstream, and the upstream Trade category, whose export-size and comparative-advantage terms are imputed for economies absent from the Comtrade reporter file, lifted their imputed share just over the threshold. Taiwan keeps 19 rankable ES and 18 rankable EO cells. In the Strategic Index the 29 policy-scored economies that lose every cell are nine territories and special administrative regions (among them Hong Kong, Macau and the West Bank and Gaza) and 20 sovereign states: the 17 above, Andorra, the Central African Republic and Grenada. The pillars are built before the rule is applied, so excluding a cell does not change the ranking of the cells that remain.

OA.3 Energy Security: further results

Rankability. The rankability rule keeps 4,163 of the 6,232 scored cells. It removes the 607 cells of the 24 territories and 1,462 cells of sovereign economies whose score rests mainly on imputation. Among the rankable cells the mean imputed weight share falls to 0.18 upstream, 0.08 midstream and 0.22 downstream. A pair holds between 68 rankable economies (Nuclear downstream) and 195 (Nuclear upstream). Within each pair every scored economy observes the same set of categories. The upstream trade baskets give Trade categories to Electric Vehicles, Wind, Solar and Nuclear upstream, so nine of the ten upstream pairs carry one; Green Hydrogen upstream is the exception.

Distribution by pair. In Electric Grid, Solar and Green Hydrogen upstream the interquartile range is narrower than 0.05. Upstream pair medians run from 0.17 in nuclear and 0.20 in batteries and electric vehicles to 0.47 in oil. Midstream and downstream the pillar rests mainly on median-centred S-curves; the four midstream pairs scored on Trade alone (gas, coal, oil and nuclear) have medians between 0.48 and 0.56. Green Hydrogen midstream, scored on Foreign Dependency alone, gives 90 per cent of its 106 rankable economies the value 0.26; Green Hydrogen downstream, scored on Consumption alone, is bimodal (interquartile range 0.10 to 0.72). Within stages, technology-stage effects explain 33, 50 and 22 per cent of the upstream, midstream and downstream variance, and country effects 51, 65 and 29 per cent of the within-pair remainder. Subtracting the contributions of Energy Prices and of the world-concentration terms of Trade and Minerals Trade leaves the pair-effect R^2 at 48 per cent.

Drivers. Investment, defined midstream only for batteries, electric vehicles, solar and wind, supplies 1.4 per cent of the midstream score against a mean effective weight of 7.0 per cent, because the investment monitor records neither manufacturing investment nor capacity for most economies (72 per cent of rankable economies score zero in the median of these pairs). Downstream, resource potential supplies 10 per cent and Investment 9.8 per cent against a weight of 19 per cent. The concentration term of Minerals Trade is constant for all economies except Taiwan and Réunion, which lie outside the World Bank list. Energy Prices scores range from 0.19 for gas to 0.81 for the electric grid, raising every economy's upstream score by between 0.025 (batteries) and 0.088 (nuclear) without changing any within-pair rank.

Correlation among categories. The median within-pair Spearman correlation between two categories is 0.42 upstream (one of 78 pair-specific correlations is negative, -0.01), 0.33 midstream and 0.11 downstream. Reserves and Production correlate at a median of 0.84 over the seven pairs that carry both, and at 0.87 among the economies with a positive score on both (a median of 16 per pair). Foreign Dependency correlates with Production at 0.76 and with Reserves at 0.69. Midstream, Foreign Dependency and Trade correlate at only 0.28 (range -0.23 to 0.48): economies with large shares of refined supply and manufacturing capacity are not always those with large export shares and small net imports. Downstream, Energy Access and Consumption correlate at

0.12 and resource potential correlates negatively with Consumption (−0.11). Within a pair the pillar's ranking follows Energy Imports (median Spearman correlation with ES_{its} of 0.80), Minerals Trade (0.79) and Reserves (0.79) upstream, Trade (0.94) midstream, and Investment (0.76) and Consumption (0.74) downstream.

Uranium. An economy with neither resources nor production scores the Energy Prices contribution, $0.704/8 = 0.088$, plus its Trade category. For the 105 economies whose uranium trade is not observed, Trade is imputed and the score is 0.172 (shared rank 67); the other 32 economies without uranium score between 0.145 (Trinidad and Tobago) and 0.201 (Norway). Their imputed weight shares lie between one quarter and one half, so all remain rankable. Producers dominate the top, though not all of it: Türkiye, which holds resources but reports no mine output, ranks 18th (0.34), and the lowest-ranked producer is 26th. Nine of the 15 highest-ranked economies are coalition members. Among the 26 members without identified resources are France, the United Kingdom, South Korea, the Netherlands, Norway and Poland.

Leaders. China's eleven first places are Batteries, Electric Vehicles and Wind upstream, where its shares of world mineral supply, production and trade dominate; Batteries, Electric Grid, Electric Vehicles, Solar and Wind midstream; and Batteries, Nuclear and Wind downstream. South Africa leads green hydrogen upstream, whose mineral weights are dominated by the platinum-group metals, and Chile the grid and solar upstream, in which copper carries most of the demand weight; in Electric Grid upstream, whose basket holds copper and aluminium inputs, the Democratic Republic of the Congo and Peru follow Chile. The midstream pairs scored on Trade alone are led by Poland (coal), South Korea (gas and oil) and Russia (nuclear, whose basket holds enriched uranium, reactor components and steam-cycle equipment). Indonesia leads Green Hydrogen midstream, in which 95 of 106 rankable economies share one value. Downstream, Qatar leads oil, Kuwait gas, Indonesia coal, Saudi Arabia solar, the United States geothermal and green hydrogen, and Türkiye electric vehicles, a pair that rests on Investment alone.

In Oil upstream (Figure 11) Saudi Arabia leads (0.81); the United States is 12th (0.71) and China 34th (0.55). The cell-constant inputs give every economy 0.16; of the gap between the top-ten mean and the pair mean, Reserves accounts for 58 per cent, Energy Imports for 28 and the country-varying part of Trade for 13. China's Reserves and Trade scores (0.64 and 0.79) are close to those of the United States (0.69 and 0.87), but its Energy Imports score is 0.25 against 0.68. In Batteries and Solar midstream China leads with 0.77 (United States 0.56) and 0.82 (India 0.67), and coalition members fill the other nine top-ten places of each, among them Indonesia and Malaysia in batteries and Thailand, Malaysia, Viet Nam and Indonesia in solar. Investment accounts for 62 and 58 per cent of the top-ten gap in these pairs (mean scores 0.13 and 0.09, top ten 0.61 and 0.58); China's lead over the runner-up comes from Foreign Dependency (0.37 against 0.21 in batteries, 0.40 against 0.28 in solar), while on Investment the United States scores higher than China in batteries (0.86 against 0.80).

The coalition's tiers. The partners, several of which enter as major suppliers, have the higher upstream mean percentile (0.63 against 0.56 for the core), while the core is ahead midstream (0.78 against 0.64) and downstream (0.64 against 0.59). The 21 EU members of the coalition are weaker upstream than the other members (0.50 against 0.64) and stronger midstream (0.79 against 0.67). By mean within-pair percentile the United States (0.95), Canada (0.89), Australia (0.82), India (0.79) and Poland (0.77) lead, and Qatar (0.44), Ghana (0.45), Gabon (0.46), Namibia (0.46) and Luxembourg (0.47) trail. Midstream, Japan has the highest mean percentile of any member (0.95), ahead of Germany, the United States, India and South Korea. Of the 1,710 member cells in the 30 scored pairs, 1,606 are rankable, 96 scored but not rankable and 8 unscored; the non-rankable cells concentrate in Namibia, Costa Rica, the Dominican Republic, Guatemala and Ghana (rankable in 13 to 15 of their 28 or 29 scored pairs) and Canada (23 of 29).

The United States, China and Taiwan. The United States leads two pairs (Geothermal and Green Hydrogen downstream); its weakest positions are 30th in Nuclear midstream, 23rd in Oil downstream, 22nd in Electric Grid midstream and 17th in Nuclear downstream. China is in the top ten of every midstream pair. Its weak positions are those of a fossil-fuel importer (33rd in gas and 34th in oil upstream, 24th in gas downstream) and two downstream pairs in which deployment data place it low: 63rd in green hydrogen and last of 186 in oil, where Consumption carries five-ninths of the weight and no rankable economy has lower projected growth of oil-fired capacity. The United States ranks above China in 8 of the 30 pairs, all upstream or downstream fossil-fuel and resource pairs and none midstream. Taiwan, scored in 28 cells and rankable in 19, has a midstream mean percentile of 0.75 (ranks 27th to 61st on Trade) and 0.01 across its seven rankable upstream pairs, with no place in any top ten.

Ties. In Green Hydrogen midstream the United States' rank of 12 is shared with 94 other economies, and in Green Hydrogen downstream 49 economies share third place at 0.72.

OA.4 Economic Opportunity: construction details and further results

OA.4.1 Construction details

Trade. Revealed comparative advantage complements market share: a small economy can be highly specialised in a basket without a large share of the world market, and specialisation is what the complexity literature reads as revealed capability. Basket export value is a second measure of scale from a source with different coverage and year. Feasibility is the forward-looking element: a country with no exports of a basket can score well if it exports products that require similar capabilities. An economy that does not report to Comtrade is scored on its two Atlas components and the world-market term. The net-import term of the ES category is not used in EO.

Production. Absolute growth rewards large producers whose output expands by the most units, relative growth rewards fast growth from a small base, and the composite balances the two; level and change each enter the category twice, directly and through the composite. In the mineral block, tonnes of different minerals cannot be added, so each mineral enters as a share of world supply weighted by the technology's share of the mineral's demand; the horizon level is divided by base-year world supply, so the change is a change in quantity, not in market share. A country the IEA supply table does not name for a mineral counts as zero there. Uranium mine output from the Red Book is scored like oil, gas and coal.

Technology Demand. Growth in the World Energy Outlook composite is absolute because a relative measure ranked across fuels would put hydrogen's near-zero base at the top; the value is a property of the technology, the same at every stage and for every economy. The BCG addressable market is ranked across the 26 cells it sizes and copied to every economy by the global-average rule. Coverage is uneven: the electric grid has no input in any source and so no Technology Demand category, electric vehicles have it only downstream, downstream batteries lack it because BCG does not size that cell, and geothermal is scored on the BCG entry alone.

Technological Readiness. The bell rises over four steps and falls over five, so an item at TRL 9 keeps a level score of $\cos(3\pi/10) \approx 0.59$ and one at TRL 3 scores $\cos(3\pi/8) \approx 0.38$; the concave momentum term gives the first step of progress the largest increment. Of the 253 mapped items, 9 map to more than one cell; 98 carry a post-TRL-9 adoption stage, 43 per cent sit at TRL 9 or above, and the 26 items that are commercial in many markets score zero on level. Of the items with a 2020 reading, 54 per cent did not move. Ten of the 33 headline cells take their technology's value because no item maps to the stage; the index differs across the three stages of ten of the eleven technologies (wind keeps one value), with a median range across a technology's stages of 0.16. The parameters (bounds 2 and 11, peak 6, momentum weight 0.3, cap of three steps, exponent 1/2) are the theme builder's defaults.

Overcapacity. Of the four midstream technologies the BloombergNEF supply-chain data cover, solar ($\rho = 2.3$, index 0.20), batteries and wind ($\rho = 3.0$, 0.13 each) sit on the steep part of the curve, and green hydrogen ($\rho = 18.2$) is effectively at zero.

Cost Competitiveness. Wages are converted at market exchange rates rather than purchasing-power parities because the price-level difference that PPP conversion removes is the cost advantage being measured. The lending rate is winsorised at its 5th and 95th cross-country percentiles before min-max rescaling; producer-price inflation enters as a rate because each country's price index has its own base year. Stale observations and gaps are filled from regional and income-group peers. The Input Cost Index carries the category wherever the LCOE and equipment cost components are absent and half of it where one is present; counting each source once avoids giving BNEF three of four votes wherever it covers a market.

OA.4.2 Further results

Rankability. Of the 2,830 cells the rule sets aside, 2,112 carry more than half of their weight on imputed components, 74 belong to territories and 644 fail on both counts. The rule bites hardest where country-specific sources are thinnest: 70.2 per cent of upstream cells are rankable, against 55.7 per cent midstream and 54.9 per cent downstream. In Batteries midstream 42 of the 54 rankable economies have an observed Foreign Dependency or Investment input, in Green Hydrogen midstream 30 of 40. The mean imputed weight share of rankable cells is 0.29. Ranked among all scored economies of their pair, cells excluded for imputation alone have a mean percentile of 0.43 (63.4 per cent below the median) and territory cells 0.42, against 0.55 for rankable cells. Both decompositions reconcile exactly (largest gaps 0 and 1.1×10^{-16}); 45.3 per cent of category scores contain an imputed component.

Distribution. Over all scored cells the midstream median is 0.454 and its lower quartile 0.328, because the zero rule places economies without recorded capacity or investment at the bottom of the clean-technology midstream pairs, and the rule removes most of them. Four of the five clean-technology midstream pairs (wind, electric vehicles, solar, batteries) have the lowest midstream medians (0.351 to 0.426). The widest boxes owe their width to one category each: in EV midstream (interquartile range 0.144) Foreign Dependency, observed for 97 of 145 rankable economies, accounts for 46 per cent of the variance (0.053 without it); in Green Hydrogen downstream (0.122) Consumption accounts for 94 per cent; in Wind downstream (0.117) Investment accounts for 46 per cent.

Variance and persistence. Technology effects alone explain 27.8 per cent of the variance and stage effects almost nothing (0.01 per cent), so a pair's level is set by its composition rather than its stage. Over all scored cells the pair share is 71.5 per cent. Across the 159 economies rankable at all three stages, the Spearman correlation of mean within-pair percentiles is 0.86 between upstream and midstream, 0.70 between upstream and downstream and 0.79 between midstream and downstream. Part of this common factor is the Input Cost Index, a country-level index whose stage variation comes only from the wage activity and the factor shares: across the 178 economies with a rankable cell, mean EO percentile and mean Cost Competitiveness percentile correlate at 0.77 (0.82 across the 57 coalition members).

Drivers. Level shares: upstream Cost Competitiveness 21.9 per cent, Technology Demand 17.3, Production 16.5 and Energy Prices 16.2; midstream Cost Competitiveness 29.2, Technology Demand 24.7 and Trade 24.6; downstream Cost Competitiveness 27.5, Technology Demand 19.7 and Technological Readiness 18.0. Within-pair variance shares: upstream Trade 26.9 and Production 22.4; midstream Trade 25.5 and Foreign Dependency 22.2; downstream Consumption 23.8 and Investment 22.2. Investment contributes 0.3, 1.2 and 4.2 per cent of the level by stage but 8.3, 12.7 and 22.2 per cent of the within-pair variance, because under the zero rule the few economies with recorded

investment stand far above the majority without it (in 9 of the 12 pairs that carry the category). The upstream constants are led by price volatility (15.9 per cent of effective weight), the TRL Index (12.5) and the addressable market (10.1). Before the rankability rule the observed country-specific share is 32.3 per cent and the imputed share 30.1 per cent.

Leaders. Chad combines low recorded wages with a 2017 lending rate of 2.45 per cent, the joint fifth lowest of the 144 rates in the cost theme; the runner-up in its three pairs is Cameroon, with the same rate (2018), and Chad's margins are 0.0020, 0.0005 and 0.0011. Canada leads nuclear upstream (0.65) and China electric-grid upstream (0.71, ahead of Chile at 0.65), the pair built on the copper and aluminium basket. The leader's margin is below 0.01 in seven pairs; the United States has the largest non-Chinese margin (0.153 over Indonesia in geothermal downstream). Coalition members hold 69.1 per cent of the 330 top-ten places; China is in the top ten of 30 pairs and the United States of 20. The United States ranks in the bottom half of one pair only, 109th of 141 in electric-grid downstream, a cost-only pair; in the mineral-based upstream pairs it ranks between third (wind) and 62nd (green hydrogen). China's one low rank, 98th of 104 in oil downstream, comes from Consumption and the growth component of Production.

The coalition. Among core members the United States (0.89), Portugal (0.84), Poland (0.84), the Czech Republic (0.81) and Spain (0.80) rank highest and the United Kingdom (0.57), Romania (0.52), Australia (0.46), New Zealand (0.34) and Ukraine (0.11) lowest; among partners, Thailand (0.82), Indonesia (0.80), Malaysia (0.79), India (0.78) and Saudi Arabia (0.66) rank highest and the Dominican Republic (0.26), Brazil (0.23), Argentina (0.19), the Democratic Republic of the Congo (0.13) and Ghana (0.10) lowest. Türkiye, Brazil, Argentina and Ghana record nominal lending rates of 39.0, 46.0, 59.7 and 27.0 per cent, at the winsorisation ceiling; with the Cost Competitiveness contribution set to its pair mean their mean percentiles would be 0.73, 0.61, 0.45 and 0.39 rather than 0.30, 0.23, 0.19 and 0.10, and Ukraine's (rate 18.9 per cent) 0.50 rather than 0.11; six members gain more than 0.2. At the top the same change would lower Portugal from 0.84 to 0.62, Thailand from 0.82 to 0.64 and Ireland from 0.71 to 0.51, while the United States barely moves. The BNEF regional composite of Technology Demand is observed for at most twelve economies and the global-average rule gives the others their mean, so a modelled economy below that mean ranks below many unmodelled ones: Australia's value is below the mean in all 18 pairs in which it is observed, the United Kingdom's in 14 of 18 and France's in 15 of 21; with Technology Demand at its pair mean their mean percentiles would be 0.52, 0.65 and 0.80 rather than 0.46, 0.57 and 0.76.

Of the core members' 1,023 scored cells 1,002 are rankable, against 716 of the partners' 858. Gabon has only 9 rankable cells, Oman 21, Saudi Arabia and Singapore 22 each, and Morocco, Namibia and Costa Rica 23. The mean imputed weight share of rankable cells is 0.20 for the core, 0.27 for the partners, 0.33 for other economies and zero for the United States, partly because the BCG addressable market is recorded for the United States alone. Within pairs the median Spearman correlation between EO_{its} and the imputed share is -0.28.

Illustrative pairs. Oil upstream is led by the United States (0.659), China (0.644), Canada (0.637), Saudi Arabia (0.622) and Norway (0.607); Saudi Arabia, Iraq, Iran, Kuwait and the United Arab Emirates share the smallest Cost Competitiveness contribution (0.095, an imputed value) and owe their places to production and trade. In Batteries midstream China (0.771) leads the United States (0.633) on Foreign Dependency (0.167 against 0.106) and Cost Competitiveness (0.142 against 0.073), while the United States' Investment contribution (0.143) exceeds China's (0.134); nine of the ten are coalition members. In Solar midstream China (0.788) is followed by India (0.640) and the United States (0.635), then Viet Nam, Thailand, Indonesia, Malaysia and the Philippines, with France and Germany eighth and ninth. In EV downstream emerging economies take eight of the ten places: China (0.755), Viet Nam (0.731), Thailand (0.705) and Türkiye (0.702) lead, because the EV-market composite, half of whose indices are growth rates (equation (75)), rewards markets growing fast from a small base; Türkiye, Viet Nam and the Philippines receive larger Technology Demand contributions than China.

OA.5 The opportunity-security space: further results

Sample. Of the 3,075 cells scored by both pillars but not rankable on both, 607 belong to territories and 2,468 to sovereign economies whose imputed weight share exceeds one half in Energy Security only (721), in Economic Opportunity only (1,006) or in both (741). The number of rankable economies per pair ranges from 40 (Green Hydrogen midstream) to 175 (Nuclear upstream). In this sample technology-stage fixed effects account for 41.9 per cent of the variance of ES_{its} and 53.4 per cent of that of EO_{its}. The six EU members below the GDP floor, which belong to the coalition only through the Union, are not counted as coalition members.

Co-movement by technology. The within-pair correlation exceeds 0.5 in 19 of the 30 pairs and is negative only in Green Hydrogen midstream. Pooled on levels it is 0.48 and on pooled within-pair ranks 0.57. The stage gradient holds within wind (0.37, 0.72 and 0.89 by stage), nuclear (0.16, 0.49, 0.89), coal (0.35, 0.56, 0.79), gas (0.40, 0.54, 0.78) and oil (0.50, 0.55, 0.75). Solar (0.48, 0.78, 0.58) and electric vehicles (0.60, 0.94, 0.80) peak midstream; in batteries the correlation falls along the chain (0.63, 0.61, 0.40); in green hydrogen the midstream value (-0.21) lies below the upstream one (0.03). Medians by technology run from 0.03 (green hydrogen) to 0.80 (electric vehicles). Upstream the correlation is positive in all ten pairs. In the five mineral pairs with a trade basket on both sides (batteries 0.63, grid 0.60, electric vehicles 0.60, solar 0.48, wind 0.37), opportunity's Trade and security's Minerals Trade measure exports of overlapping materials and correlate at 0.70 to 0.85. The fossil-fuel pairs follow (oil 0.50, gas 0.40, coal 0.35); nuclear (0.16) has half of its economies at one security value, and green hydrogen (0.03), the only upstream pair without a trade basket, rests on platinum-group endowments on the security side and on cost, demand, readiness and production on the opportunity side.

Shared components. A component counts as shared when the other pillar contains a component of the same category with identical observed values: every component of Consumption, Energy Access, Investment and Energy Prices, two of the three security and two of the five opportunity components of Trade, and five of the six components of Foreign Dependency in each pillar; no Production component. In seven downstream pairs (batteries, coal, electric vehicles, gas, green hydrogen, nuclear, oil) the security score is a reweighting of part of the opportunity score, which is why Green Hydrogen (0.92) and Nuclear (0.89) downstream show some of the highest correlations. The non-shared median correlation has an interquartile range of 0.20 to 0.40, a 45 per cent reduction from the full pillars. The level covariance is positive in all 30 pairs, including Green Hydrogen midstream. Of the pooled within-pair covariance, the two cross terms of equation (49) account for 24 per cent and the non-shared term for 16 per cent (58 per cent upstream, nothing downstream); in the median pair the shared term accounts for 19 per cent. The cross terms are not definitional but run through shared inputs.

The non-shared rank correlation is 0.37 midstream and 0.30 upstream. The pillars' distinctive trade components (net imports and, upstream, minerals trade for security; revealed comparative advantage, export size and feasibility for opportunity) all reward exporters of the stage's basket; removing opportunity's trade components as well lowers the medians to 0.15 midstream and 0.02 upstream. In the three downstream pairs where it can be computed (geothermal, solar, wind) it is -0.04.

Category correlations. Consumption, Energy Access and Investment correlate perfectly with their counterparts; Trade, sharing two components, 0.62; Production, from different sources and transformations of the same physical quantity, 0.27; and Foreign Dependency, whose shared components are missing for many economies and imputed under different rules, 0.04. The median correlation between categories with different names is 0.14 over 47 category pairs. Technology Demand and Cost Competitiveness have absolute correlations of at most 0.12 and 0.17 with every security category (the most negative is Cost Competitiveness with Reserves, -0.17). Within security, Production and Reserves average 0.79 across seven upstream pairs (0.72 to 0.91 in the six critical-mineral pairs, where 62 to 85 per cent of rankable economies record zero on both); Nuclear upstream has the lowest value (0.61), because many holders of uranium resources do not mine them.

Regions. Laggards outnumber leaders because a tied cell at a median counts as low and ties are common where a pillar rests on a zero-anchored component. Across pairs, the observed share of opportunity without security tracks the copula-implied one (correlation 0.90). Off-diagonal shares are 19.5 and 17.2 per cent upstream, 13.8 per cent (opportunity without security) midstream, and 12.4 and 10.2 per cent downstream; by technology the leapfrog share runs from 9.5 per cent (electric vehicles) to 20.2 per cent (green hydrogen and nuclear). In Green Hydrogen midstream 34 of 40 economies share the lowest security value, which is also the median; in Nuclear upstream 87 of 175 share 0.172, the median, and 37 of the 49 cells in the leapfrog region are such economies. Counting ties as high empties the region in Green Hydrogen midstream and lowers it to 6.9 per cent in

Nuclear upstream. The next pairs, Green Hydrogen upstream (24 per cent), Coal upstream (22) and Batteries downstream (21), have few ties and shares near the copula value.

The coalition. The partners, many of them major suppliers, have 21.4 per cent of cells with security but not opportunity. The median core member has 16.7 per cent of its pairs in the leapfrog region, the median partner 6.9 per cent. Austria, Portugal, Luxembourg (11 of 30 each), Ireland (10) and Croatia (9) lead; without the two tie pairs their counts are 9, 10, 10, 8 and 7. Among partners the largest counts are Thailand and the Philippines (5 of 29), then Malaysia, Viet Nam and Qatar (4). Thirteen members have no leapfrog pair: Canada, Japan, the United Kingdom, Australia and Ukraine in the core, and Türkiye, Brazil, Argentina, the Democratic Republic of the Congo, the Dominican Republic, Gabon, Namibia and Ghana among partners. Brazil, a partner on its reserves alone, is the clearest case of security without opportunity. The pairs most often in the leapfrog region across members are Gas and Oil upstream and Green Hydrogen midstream (14 members each), Coal upstream (13), Solar downstream (12), Nuclear upstream (11) and Grid upstream (10); without the two tie pairs the coalition share falls from 12.8 to 11.8 per cent. Members' rankable pairs number 22 to 30 in the core and 9 to 29 among partners, so the shares of Costa Rica, Gabon, Namibia (9 pairs), Guatemala (10), the Dominican Republic and Ghana (11) rest on few cells.

Within countries. Of the 174 countries with a Strategic Index, seven with fewer than five cells are left out; the remaining 167 have 5 to 30 cells (median 22; 50 have fewer than ten). The correlation is positive for 164 countries; the three exceptions (Afghanistan, Bhutan, the Maldives) are not members. Among members it averages 0.52, from 0.27 (New Zealand) to 0.77 (Viet Nam). Security varies more than opportunity across a country's sectors (mean standard deviations 0.15 and 0.07); the covariance share ranges from 16.5 per cent (Ghana) to 66 per cent (India) among members, and the standard deviation of Δ_{its} from 0.068 (Lao PDR) to 0.26 (the Gambia). The pairs' mean pillar values are only weakly related across pairs (0.33); after subtracting pair means the within-country correlation rises to 0.67 and the standard deviation of the gap falls to 0.08, so part of the gap's spread is common to every country.

The Strategic Index and the regions. Every Strategic Index cell (3,154 for 174 countries) lies in this sample. A country's top sector, before eligibility rules, lies in the leapfrog region for 47 of 174 countries (27.0 per cent; 15 members), against 15.2 per cent of cells. Nuclear upstream is the top sector of 62 countries, 43 of them at the common security value, which gives a large need whichever side of the opportunity median they fall. After the endowment screen, 169 countries keep an eligible cell and for 35 of them (20.7 per cent) the top one lies in the region. Of the 57 allied picks (43 midstream), the eight in the region are Austria, Belgium, Italy, the Netherlands, Romania and Viet Nam in Batteries midstream and Indonesia and Slovakia in Nuclear midstream; 21 are leaders, 14 have security without opportunity and 14 are laggards, while 61.0 per cent of eligible sectors are leaders. None of the eight Nuclear upstream picks is in the region: all eight members hold or mine uranium. Costa Rica, the Dominican Republic and Guatemala have four

eligible sectors each (nuclear, oil, gas and coal midstream) and Namibia five (the same and Nuclear upstream). Midstream nuclear security is built from Trade alone and compressed around its median (quartiles 0.435, 0.482, 0.530), so their security ranks of 0.50 to 0.71 lie at or above it, and the technology weight (nuclear 0.999, gas 0.422, coal 0.024, oil zero) favours nuclear.

Caveats. Percentile ranks discard distances, and the median split turns small differences into differences of region; where many economies tie at a median the convention decides the region of the whole group (counting ties as high lowers the upstream leapfrog share from 19.5 to 15.5 per cent and the coalition's from 12.8 to 10.8). Regions are relative to the rankable economies of each pair, a set that leans towards economies with good statistical coverage. The rank-based measure of mechanical overlap covers 23 pairs; the covariance decomposition covers all 30 but concerns levels and is dominated by the pairs with the largest covariances. Within-country statistics compare category bundles that differ across pairs. The endowment screen is a rule for the allied picks, not part of either pillar or of the index. More generally, shared components make the implied trade-offs of a composite hard to see in the aggregate (Ravallion, 2012); inspecting the correlation structure among indicators (Nardo et al., 2008) is what reveals them here.

OA.6 Coalition rule: data and further results

Supply and reserves measures of the supplier route. An economy passes the supplier test if, in at least one Upstream or Midstream stage of a headline technology, it holds at least 5 percent of the world total of one of the following supply measures, or at least 10 percent of world reserves of a resource the stage extracts. Supply: exports of the stage's HS6 basket (2023; The Growth Lab at Harvard University, 2019); oil, gas and coal production (2025; Energy Institute, 2026); uranium mine production (2024, OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026); mine production and refining of the minerals a technology uses (2025; International Energy Agency, 2026a, with manganese, zinc and platinum-group metals from the Energy Institute); and clean-technology manufacturing capacity (2024). Reserves: the critical-mineral reserves of U.S. Geological Survey (2026) at the end of 2025 (cobalt, lithium, graphite, rare earths, copper, manganese, nickel, zinc and platinum-group metals; the report's erratum puts Brazil's rare earths at 11 Mt), proved oil, gas and coal reserves at the end of 2020 (Energy Institute, 2026) and identified uranium resources recoverable below USD 260/kgU (OECD Nuclear Energy Agency and International Atomic Energy Agency, 2026). Holders whose reserves USGS does not quantify (entries NA, W or s) count as zero, so world shares are measured on quantified holdings. The route reads the same reserves tables as the Reserves category of the Energy Security pillar (Section 5). The 10 percent bar binds for a small group: six economies that are not China-leaning hold between 5 and 10 percent of a world reserve without otherwise qualifying (Madagascar 8.7 percent of graphite, Mozambique 8.1 percent, Kuwait 5.9 percent of oil, Tanzania 5.8 percent, Niger 5.7 percent of uranium, New Caledonia 5.1 percent of nickel), as do Iraq, Turkmenistan and the United Arab Emirates, which are China-leaning.

GDP floor. The floor of USD 100 billion (current dollars, latest year, 2025 for every member) excludes 18 U.S.-leaning economies, among them six EU members and small European and Pacific states, and 16 members of the five agreements, the largest Lithuania (USD 95 billion), which enters through the EU node, and Panama (USD 91 billion). Puerto Rico inherits the U.S. position and exceeds the floor but has no vote of its own and is not a member.

Supply cover of the coalition. Across the 18 Upstream and Midstream stages with an HS6 basket, the 63 economies of the coalition (the 57 members and the six EU members below the GDP floor) account for a median 70.7 percent of world exports, from 45.2 percent in Wind Upstream to 88.4 percent in Batteries Upstream, and China for a median 17.6 percent, with a maximum of 40.9 percent in Batteries Midstream. The coalition's share exceeds China's in all 18 stages, but in two Upstream stages the excluded China-leaning suppliers other than China hold large shares: 31.3 percent of Wind Upstream exports (coalition 45.2) and 47.6 percent of Nuclear Upstream exports (coalition 50.0). Coalition economies mine 81.9 percent of the world's cobalt, 79.4 percent of its nickel, 60.0 percent of its lithium and 54.5 percent of its copper, but 3.6 percent of its graphite and 14.3 percent of its rare earths; they refine 17.4 percent of cobalt, 23.2 percent of copper, 24.6 percent of lithium, 5.5 percent of graphite and 12.6 percent of rare earths, against China's 75.6, 46.8, 73.7, 94.4 and 83.9 percent; nickel refining is 55.7 percent in the coalition. Coalition economies hold 75.8 percent of quantified world cobalt reserves, 77.3 percent of lithium, 85.5 percent of manganese, 78.8 percent of nickel and 83.9 percent of platinum-group metals, but 33.3 percent of rare earths (China 58.4) and 35.7 percent of graphite (China 32.3). In oil and gas the excluded China-leaning suppliers other than China hold about as much as the coalition or more (35.3 against 35.7 percent of oil reserves, 43.4 against 30.8 percent of gas).

Dyadic alignment among members. Counting EU members individually, the 1,596 pairs of members split 29.3, 64.8 and 5.8 percent across $A_{ij} = 1$, $\frac{1}{2}$ and 0. The three China-leaning partners have $A_{ij} = 0$ with every core member and $A_{ij} = 1$ with China and Russia.

Sensitivity of the blocs. With session 78 alone (192 economies; Spearman 0.966 with the headline, 89.1 percent in the same bloc), New Zealand falls just below the U.S.-leaning cut ($s = 0.583$ against 0.584) and becomes a partner through IPEF, Saudi Arabia becomes China-leaning and loses its supplier route, Myanmar becomes nonaligned and enters as a supplier, and India becomes China-leaning but remains a partner through IPEF and the MSP. With the final-passage series (sessions 76–80, 193 economies, 89.6 percent in the same bloc) the cuts move to 0.446 and 0.055: China-leaning economies cluster more tightly around China in final-passage votes, and Russia ($s = 0.117$), Kazakhstan (0.056) and Myanmar (0.163) would enter the coalition as major suppliers; Malaysia becomes China-leaning but stays through IPEF.

The earlier hand-picked list. Of the 23 members fixed by hand in an earlier version, the United States, Canada, Japan, Australia, Korea, the United Kingdom, Germany, France, Italy, Norway and

Denmark are core members, and India, Mexico, Brazil, Saudi Arabia, South Africa, Indonesia, Viet Nam, Argentina, Morocco and Chile are partners. The United Arab Emirates (largest supply share 4.2 percent, oil reserves 5.6 percent) and Kenya leave. The 16 new partners are Colombia, Costa Rica, the Democratic Republic of the Congo, the Dominican Republic, Gabon, Ghana, Guatemala, Malaysia, Namibia, Oman, Peru, the Philippines, Qatar, Singapore, Thailand and Türkiye.

OA.7 The Policy index and the Strategic Index: further detail

Tagging and strength of IEA policies. Each policy of the IEA Policies and Measures database (International Energy Agency, 2026e) is assigned to technologies first from its own technology list and, failing that, from keyword rules applied to its title and text; a policy matched to no technology is cross-cutting and counted in every technology. Stages are assigned by keyword rules on the text: Upstream on whole words for mining, mines, exploration, extraction, ores, leases, concessions and drilling; Midstream on processing, refining, smelting, manufacturing, factories, plants, components, supply chains and domestic content; Downstream on deployment, installation, consumers, end use, adoption, efficiency, demand, charging, grid connection, power plants and generation. A policy that matches no stage is cross-cutting across the three. Its strength is $\sigma_h = w_{\text{type}}\, w_{\text{status}}\, w_{\text{juris}}\, w_{\text{tech}}\, w_{\text{stage}}$ with type weights 0.85 (financial incentives), 0.70 (public procurement), 0.50 (regulations and standards; research, development and demonstration), 0.20 (information and labelling; other) and 0.10 (voluntary and coordination measures); status weights 1 (in force), 0.60 (planned), 0.50 (proposed), 0.20 (expired or unknown) and 0 (ended); jurisdiction weights 1 (national), 0.66 (international), 0.50 (subnational, state, provincial or regional), 0.30 (unknown) and 0.25 (local); a technology discount of 0.70 for a cross-cutting policy and 0.30 for a technology found only in the text; and a stage discount of 0.75 for a cross-cutting stage. A policy counted in several cells carries its full strength in each. Upstream words are matched as whole words, because as substrings "ore" and "mine" match "more", "Korea" and "determine".

The Climate Action Tracker component. The Tracker rates 65 economies in the final build: 39 in their own right and 26 EU members through the Union's rating. Forty are rated insufficient, nine critically insufficient, six highly insufficient and ten almost sufficient; among the 46 rated coalition members the counts are 31, 7, 4 and 4. Because the component varies across a country's cells only through g_t, it tilts the within-country policy ranking. Within the Strategic Index sample the median within-country Spearman correlation between POL^*_{its} and g_t is 0.82 for the 40 countries rated insufficient and 0.86 for those rated almost sufficient, -0.92 for the nine rated critically insufficient, and 0.12 for the 103 countries scored on the IEA component alone. The IEA component itself is uncorrelated with g_t within a country (median -0.07 for the 65 countries rated by the Tracker). The mean Policy index is 0.64 for the economies scored on both components and 0.39 for those scored on the IEA component alone; the IEA component distinguishes a median of 31 values among the 33 cells of the first group and 11 among those of the second. The index enters

the Strategic Index only through within-country ranks, so these level differences do not move one country against another.

Technology weight. The lifecycle medians are 820 gCO_2e/kWh for pulverised coal, 490 for gas combined cycle, 48 and 41 for utility and rooftop photovoltaics, 27 for concentrated solar, 38 for geothermal, 12 for nuclear and 11 and 12 for onshore and offshore wind (Schlömer et al., 2014); oil-fired generation takes the SRREN median of 840 (Moomaw et al., 2011) in place of the 720 of the input file, because AR5 reports no oil row. Technologies without a row take proxies: batteries the solar value, the grid the mean of solar and wind, green hydrogen the mean of gas and solar, and electric vehicles the mean of six generation technologies. The resulting g_t is 0 (oil), 0.024 (coal), 0.422 (gas), 0.569 (electric vehicles), 0.694 (green hydrogen), 0.967 (solar, batteries and geothermal), 0.983 (grid), 0.999 (nuclear and wind). The sector prior $0.1\lambda_s + 0.1g_t$ spans 0.025 to 0.175; the gap between oil and wind in the technology term (0.100) is twice the gap between adjacent stages (0.025 to 0.05).

Sample. Of the 6,918 country–sector rows of the output, 442 belong to countries without a Policy index and 6,476 to policy-eligible countries. Among the latter, 1,000 fail because the Economic Opportunity cell is not rankable, 721 because the Energy Security cell is not rankable, 979 because neither is, and 622 because the Energy Security cell is missing; 3,154 are scored. Before the Upstream trade baskets were added on 11 October 2026 the index covered 192 countries; the new Trade category of the Upstream cells is imputed for many small economies and pushes their cells over the imputed-share threshold, which leaves 174. Sector fixed effects explain 72.6 percent of the variance, technology fixed effects 67.5 percent, stage fixed effects 4.2 percent and country fixed effects 4.4 percent. The highest sector means are Solar Upstream (0.634), Batteries Upstream (0.631), Nuclear Upstream (0.620) and Batteries Midstream (0.618), the lowest the coal and oil stages (0.410–0.441). Upstream cells have the highest mean need (0.677, against 0.513 Midstream and 0.552 Downstream).

The endowment screen. An Upstream cell carries a resource base if the technology-level variable of the Reserves or of the Production category of the Energy Security pillar (for instance the uranium resources and mine production behind Nuclear Upstream) is positive for the country; every technology with such a variable is screened. Unquantified USGS holdings count as zero in these technology roll-ups. Cells without a resource base carry `resource_base` FALSE and the pick exclusion "no resource base" in the output; their index values are unchanged. Of the 41 picks the screen changes, the forgone index has median 0.026 (interquartile range 0.016–0.040); 16 picks are unchanged. Every Nuclear Upstream pick under the screen lies in a member with identified uranium resources (Chile, the Democratic Republic of the Congo, Finland, Gabon, Greece, Japan, Saudi Arabia and Sweden).

Variants of the Strategic Index. Each variant recomputes the index over the headline cells with the endowment screen kept. Within-member Spearman correlation with the headline (median),

identical picks and members whose headline pick is in the variant's top three: security as strength 0.36, 5 and 12 of 57 (core 0.38, partners 0.24, negative for ten partners); strength without the fixed weights 0.01, 1 and 9; need without the fixed weights 0.90, 31 and 49; opportunity and need ranked within the country 0.89, 20 and 49; no policy term 0.88, 30 and 55; policy from the IEA component alone (the 46 members scored on both) 0.89, 34 and 42; the October 2026 NIPO component added back (50 members) 0.96, 27 and 44. The NIPO variant uses a GTA NIPO extract of October 2026 (measures in force on 5 October 2026, refreshed on 13 October with the debiased strength measure), built exactly as the pipeline builds the NIPO Policy Index rows: 77 jurisdictions with EU members individually, 939 rows in the headline technologies, all of them economies that already have a Policy index; NIPO enters with weight 4 beside IEA PAMS (3) and CAT (2), renormalised over the components present. The component stored with the February 2026 data covered only 23 economies. Requiring both policy components (`OPSI_POLICY_REQUIRE_ALL=1`) leaves 65 eligible countries and 1,666 Strategic Index cells, identical to the headline in value; 46 members keep their pick and the 11 scored on the IEA component alone have none.

OA.8 Bilateral partnership indices: further detail

Trade components. The reconciled flow matrix holds, for each exporter, importer and technology–stage cell, the flow in 2020 and 2024: the importer's declaration where the importer reports the cell in that year, and otherwise the exporter's declaration times 1.06, the conventional CIF/FOB margin. An economy that reports a cell but no flow with a partner records a zero; a pair in which neither side reports is unobserved. The growth term is defined only where both years are observed and the 2020 flow is positive; a dyad that trades only in 2024 is scored on its level. The first-stage ranking runs over dyads with a positive flow in either year, and the second ranks them within the reporter, with recorded zeros as one tie block below every trading partner (so they take the block's mid-rank). A dyad without an observed 2024 flow takes the mean of the observed values in its cell and counts as imputed in the rankability measure; in the 15 cells without an HS6 basket (every Downstream cell and the Upstream and Midstream stages of Geothermal and Green Hydrogen) every dyad carries the constant 0.5, which ranks nothing and is left out of the imputed-share measure. The Comtrade dyads have 168 reporters in 2020 and 143 in 2024, and 208 economies appear as reporter or partner. Core members' imports are almost all self-declared (0.3 percent of their observed import components are mirrors; 5.2 percent of their components are imputed). Dropping the mirror fill and re-running every later step leaves the headline PSI_j almost unchanged (Spearman 0.997, median rank change 1, largest 35, the same top fifteen) but moves C_j^{PO} (Spearman 0.816), because a third of the core exporters' observed export flows are mirrors of their markets' own import declarations; the United Arab Emirates (91st to 126th) and Russia (105th to 117th) would lose most.

Outward investment. The IMF indicator is outward direct investment, assets (gross), debt instruments, all entities, reported official data. A position is a stock, so the reported years are

averaged; an absent record is missing, while a reported zero is a real zero and joins a tie block below every positive position before the within-reporter ranking. The 16 conduit centres are the ten economies that host more than 85 percent of phantom FDI according to Damgaard et al. (2024) (the Netherlands, Luxembourg, Hong Kong, the British Virgin Islands, Bermuda, Singapore, the Cayman Islands, Switzerland, Ireland and Mauritius) and six offshore centres excluded before (the Bahamas, Barbados, the Turks and Caicos Islands, the Isle of Man, Guernsey and Cyprus); positions in which a centre is reporter or counterpart are unobserved. Before the list was extended the Netherlands and Singapore were the second and third Friendshore partners of the United States on the strength of pass-through positions. The United States' largest outward counterparts are now the United Kingdom, Australia, Taiwan, Malaysia and Canada. In the four CM-FDI cells the tie is built from the projects used by the index measures (Bandara and Net Zero Industrial Policy Lab, 2026): manufacturing projects that are announced, under construction, completed or operating (cancelled, paused and closed plants are dropped), with a home economy other than the destination; a joint venture attributes half of the project to the listed parent. Attributed counts and disclosed capital are ranked within the cell over the dyads with a project and averaged, then ranked within the reporter with partners without a project as one tie block below; a reporter with no project in the cell has the component missing. Because the ties are sparse, 7.2 percent of the dyad cells in these four cells carry an investment component, against 19.5 percent elsewhere (18.1 percent overall); 29 economies invest (18 of them core members). Reporter need is missing in 12.5 percent of Friendshore cells, among them every cell of Electric Grid Downstream and the two Geothermal stages.

Chinese-parent exposure by partner. Among the heavily exposed partners are Türkiye (batteries 1.00, solar 0.97, electric vehicles 0.82), Thailand (batteries 0.97, electric vehicles 0.88), Malaysia (electric vehicles 0.90), Viet Nam (electric vehicles 1.00), Indonesia (solar 0.85), Saudi Arabia and Oman (solar 1.00), and among the core Korea (batteries 0.91, wind 1.00), Hungary (electric vehicles 0.64, batteries 0.55) and Slovakia (electric vehicles 0.61). The United States (at most 0.27, in solar), Canada and Mexico (zero in batteries) are among the least exposed. Of the 94 partner–technology cells outside China, Hong Kong and Macao, 48 are at 0.5 or above and 19 at zero. Where defined, the component contributes 0.051 to the composite on average (8.1 percent). Partners with a share of at least one half lose 0.063 of their core-view Friendshore rating on average, those below 0.2 gain 0.043. Without the component Hungary would rise from 20th to 16th in the headline PSI_j, and Denmark and Finland would fall three places.

Climate penalty. The Tracker rates 65 economies (39 national ratings and the EU's rating for 26 members). Forty of them are rated insufficient, so the median rating given to every unrated economy is 0.75, and the penalty is a common value, $0.15(1 - g_t)$ for Friendshore and $0.0375(1 - g_t)$ for Opportunity, for every dyad of unrated or insufficient parties; the within-cell ranking removes it. The largest penalties, for parties rated almost sufficient, are 0.200 and 0.050 for oil, 0.195 and 0.049 for coal, 0.116 and 0.029 for gas, 0.086 and 0.022 for electric vehicles and 0.061 and 0.015 for

Table OA.4: WDI series in the development basket and their orientation

Orientation	Series (WDI code)
Higher is better (27)	Access to electricity (`EG.ELC.ACCS.ZS`); ten B-READY pillar scores: business entry, business insolvency, business location, dispute resolution, financial services, international trade, labor, market competition, taxation, utility services (`IC.BRE.*.OS`); control of corruption, government effectiveness, political stability, rule of law (percentile ranks, `CC/GE/PV/RL.PER.RNK`); domestic credit to the private sector, total and by banks (`FS.AST.PRVT.GD.ZS`, `FD.AST.PRVT.GD.ZS`); external balance on goods and services (`NE.RSB.GNFS.ZS`); FDI net inflows (`BX.KLT.DINV.WD.GD.ZS`); GDP growth (`NY.GDP.MKTP.KD.ZG`); GDP per capita (`NY.GDP.PCAP.KD`); gross capital formation (`NE.GDI.TOTL.ZS`); high-technology exports (`TX.VAL.TECH.MF.ZS`); human capital index (`HD.HCI.OVRL`; no observation in 2022–2024); industry value-added growth (`NV.IND.TOTL.KD.ZG`); tax revenue (`GC.TAX.TOTL.GD.ZS`); trade openness (`NE.TRD.GNFS.ZS`).
Inverted (13)	Bank liquid reserves to assets (`FD.RES.LIQU.AS.ZS`); bank capital to assets (`FB.BNK.CAPA.ZS`); deposit interest rate (`FR.INR.DPST`); net energy imports (`EG.IMP.CONS.ZS`); external debt stocks (`DT.DOD.DECT.GN.ZS`); total debt service (`DT.TDS.DECT.GN.ZS`); public and publicly guaranteed debt service (`DT.TDS.DPPF.XP.ZS`); central government debt (`GC.DOD.TOTL.GD.ZS`); firms experiencing electrical outages (`IC.ELC.OUTG.ZS`); net bilateral aid from the United States (`DC.DAC.USAL.CD`); net ODA received per capita (`DT.ODA.ODAT.PC.ZS`); applied tariff rates, all and manufactured products (`TM.TAX.MRCH.WM.AR.ZS`, `TM.TAX.MANF.WM.AR.ZS`).
Excluded (4)	Consumer price index (`FP.CPI.TOTL`); net foreign assets in local currency (`FM.AST.NFRG.CN`); net trade in goods, current US$ (`BN.GSR.MRCH.CD`); energy use per capita (`EG.USE.PCAP.KG.OE`, used as $d^{(8)}$).

Notes: Series as in `data/raw/wb_wdi.csv`; orientation and exclusions as in `partnership_strength_build_development_indicators()`. Series are averaged over 2022–2024 and S-curved across economies before inversion and averaging.

green hydrogen; for the clean technologies they are below 0.01. Among the ten leading Friendshore partners of the United States and Japan the penalty averages 0.018 and 0.033.

Development Potential inputs. The development index $d^{(1)}$ averages, over the series observed for each economy, the S-curves across economies of 2022–2024 means of a 40-series WDI basket (World Bank, 2026) (Table OA.4), with 13 series inverted, and ranks the mean. Coverage is uneven: the ten B-READY series are observed for 50 economies, central-government debt for 51 and electrical outages for nine, against more than 200 for GDP per capita or the governance percentiles; the human capital index has no observation in the window. The business environment uses the Doing Business score of 2019 (World Bank, 2020), the last release with broad coverage, although the series was discontinued (World Bank Group, 2021). Aid is the sum over donors and the years 2013–2023 of constant-price ODA disbursements from the OECD Creditor Reporting System (OECD, 2026) (44 official donors),

$$A_{js} = \max\Big(0,\ \sum_{d}\sum_{y}\Big[\sum_{\sigma\in\Sigma_s^+} a^{\sigma}_{dj,y} - \sum_{\sigma\in\Sigma_s^-} a^{\sigma}_{dj,y}\Big]\Big), \tag{OA.4}$$

with Σ_s^+ the stage's sector (industry for Midstream, energy for Downstream, mineral resources and mining for Upstream) and Σ_s^- the coal and upstream oil-and-gas sub-rows for Upstream; $d^{(6)}$ and $d^{(7)}$ rank A_{js} and A_{js}/Y_j within each stage. Stage aid is observed for 121 (Upstream), 131 (Midstream) and 131 (Downstream) of the 132 partners. Several orientations are choices: high bank capital and liquidity ratios are read as under-intermediation; ODA received is inverted inside $d^{(1)}$ (aid dependence) but enters positively in $d^{(6)}$ and $d^{(7)}$ (existing engagement); energy use per capita is read as the depth of the energy system. The donor is not matched to the reporter, so DP is not reporter-specific.

Rankability of partners. A cell's imputed weight share is the share of its partner- and pair-specific component weight resting on imputed or missing inputs: a trade component imputed at the cell mean, a missing investment position, an alignment assigned rather than read from both countries' own votes, a missing development indicator, and, for components read off the partner's pillar cells, those cells' own imputed share. The reporter's own attributes, the trade component of cells without a basket and the penalties are left out. A dyad's share is the mean over the five cells of its best-five summary, and the PSI averages and weights the shares as it does the scores. The median Friendshore dyad share is 0.42 over all reporters and 0.26 over the core members. In the core view the ranked partners' shares have median 0.20 (maximum 0.42); the highest-scoring unranked partners are territories such as Guam.

Further results. The market score C_j^{PO} follows the core members' observed exports to the market (Spearman 0.82) and correlates negatively with the market's own security need (-0.54), although need enters it with a positive weight, because the economies most in need of supply are mostly small importers. The strongest friendshoring–weak market contrasts are small European states and some low-income economies (San Marino, Andorra, Albania, Chad, Niger); the reverse are markets such as the United Arab Emirates (17th on C_j^{PO}, 132nd on C_j^{FS}), Kazakhstan, Liberia and Uganda. The Spearman correlations among the category scores are 0.59 (C^{FS} and C^{PO}, 192 partners), 0.31 (C^{FS} and C^{DP}) and 0.29 (C^{PO} and C^{DP}, 130 partners); Opportunity accounts for 14.5 percent of the variance of PSI_j among the 62 ranked partners without Development. High-income partners average 0.827 and the other partners on the World Bank list 0.672. Without the alignment component, 19 rather than 24 core members would be in the top 25, and China, Saudi Arabia and Indonesia would replace Sweden, Korea and Ireland in the top fifteen; Viet Nam would rise from 64th to 20th, the United Arab Emirates from 91st to 21st and Oman from 140th to 59th. The world view's top fifteen add China, India, Indonesia, Viet Nam and Malaysia and drop Belgium, Poland, Czechia, Sweden and Ireland; in the full-coalition view China is 9th and India 15th. Comparing friendshoring and market views, the pair means agree at 0.733 over 3,192 ordered coalition pairs, and the mean within-cell partial correlation given the shared EO term is 0.44; for the 2,070 pairs with a nonaligned member the two agree on average (0.016). The pairs the market view favours most are in opposite blocs, such as the edge from Luxembourg to Oman (FS = 0.37 against PO = 0.71) and from Indonesia to Canada (0.42 against 0.75); those the friendshoring view favours most have Ukraine as the partner, of Greece (0.70 against 0.23) and Sweden. After Canada's rating of the United States, the highest dyadic PSI_{ij} are Spain's of Portugal, the United States' of the United Kingdom, and Austria's and Czechia's of Germany (0.970–0.976). The Development leaders after China are Serbia, Rwanda, Viet Nam, North Macedonia and Mauritania (0.872), with best cells 40 percent Upstream, 26 percent Midstream and 34 percent Downstream.

OA.9 The Allied Industrial Base: further results

Nodes and data quality. Of the 92 nodes, 23 are of high confidence, 68 usable with caution and one insufficient for optimization (cobalt ores and concentrates). The caution flags are mirror flows above 30 percent of value, comparative advantage missing for exporters with 20 percent or more of exports, codes kept with a caveat or shared with another node (wafers, HS 3818.00, also counted in Semiconductors), HS revisions without a 2020 equivalent, and production far more concentrated than trade. Five cells are shared physical nodes: permanent magnets, rare-earth compounds and rare-earth metals (Electric Vehicles and Wind), transformers (Electric Grid and Solar) and pipelines (Oil and Gas). Eleven nodes have credible physical data: anode materials, battery cells, cobalt and nickel refining, lithium chemicals, natural graphite, rare-earth metals, rare-earth compounds (with the monazite ores merged into them), polysilicon, solar cells, solar modules and wafers.

Validation chains. Four nodes are traced through every step under both supply constraints (Table OA.5); they report what the model produced, and nothing was tuned to them. Permanent magnets have no physical proxy, so the two modes agree: China's removal costs 52.4 percent of the allied scope's traded demand, existing relationships and optimized trade both restore half of it, the coordination dividend is zero and the node is BUILD, in the motors-and-magnets compact whose critical supply partner is the United Kingdom. Rare-earth compounds are BUILD in both modes: under hold the concentrates that Myanmar and Laos sell to China stay with China, and in the production-constrained mode the exporters absent from the IEA refining data cannot expand, so the gap, 38.2 percent, is separation capacity; Japan, Malaysia and the United States form the minimum coalition. Anode materials lose 59.4 percent of their supply and keep a gap of 58.3 percent; with natural graphite they form a compact in which Madagascar and Mozambique are critical supply partners. Wafers show what the physical rule changes. On trade alone, semiconductor wafers from Japan, Taiwan and Korea appear to replace Chinese solar wafers, coverage reaches 93.4 percent and the node is LOW INTERVENTION with the physical-capability warning; with solar-wafer capacity deciding who can supply, coverage stops at 74.5 percent and the node is BUILD, with silicon metal and solar cells in a compact of India, Japan, Korea, Thailand, Turkey and Taiwan.

The investment step. In the headline, 53 nodes have a residual gap of at least 5 percent, 49 of them in the electro-industrial scope, with up to 20 eligible hosts each (a median of 20, at least 11). The leading hosts qualify on comparative advantage at material scale in 41 nodes, on production shares in five, on both in one and on world export share in two. A 10 percent increment at the leading host lowers the median residual gap from 18.7 to 8.7 percent and closes it in 10 nodes; the smallest gain of a leading host is 5.9 points, where the gap was smaller than the increment. The increments of 5 and 20 percent are in `allied_investment_partnerships.csv`.

Coalitions. The exact and greedy coalitions have the same size in all 22 compacts and the same members in 13. Associate partners, the additions that reach 99 percent, are needed in one compact

Table OA.5: Validation chains for four nodes, China removed, hold, reallocation. Mode: production-constrained (PC, the headline) or trade-only (TO). Exposure, existing (state B) and optimized (state C) coverage and the residual gap in percent of the allied scope's traded demand; dividend in points. Compact: the compact the node belongs to and its exact 95% coalition, critical supply partners in bold. The cases report what the model produced; nothing was tuned to them. Source: `allied_trade_stress_test.csv`, `aib_node_classification.csv`, `aib_compact_candidates.csv`; `scripts/paper/fig_aib.R`.

(Thailand, in motors and magnets); in the other 21 the 95 percent coalition already reaches 99 percent. Critical external dependencies are reported in seven compacts; the full leave-one-country-out test, for every supplier of every node, is in `aib_compact_leave_one_out.csv`.

OA.10 Robustness and validation: further detail

Reproduction. The weighting experiments use a re-implementation of the available-case mean of equation (16) on the stored category scores, which reproduces the stored indices at the configured weights to within 10^{-15}; the curvature, imputation and data-choice experiments rebuild both pillars from the theme tables with the pipeline's builders and configuration; the Strategic Index and the Policy index are rebuilt with the pipeline's own functions. Each reproduces the stored values exactly at the baseline settings. Table OA.6 collects the within-pair correlations of the pillars.

Vintages. A separate build re-derives both pillars as of 2020 and 2025 by slicing the time-varying sources (the EI Statistical Review, the Atlas of Economic Complexity, GCIM investment, and the IMF and ILO price, rate and earnings series) to each year, holding the other themes (resource potential, reserves, the IEA critical-mineral and clean-technology tables, the mineral production sheets, BNEF demand, levelised costs, overcapacity and technology readiness) identical, and measuring Trade on the Atlas basis. Categories carrying 52 per cent of the nominal ES weight and 70 per cent of the EO weight are time-varying by classification, those whose scores differ in at least one per cent of their cells 40 and 50 per cent, and, after renormalisation over observed

2025 vintage against headline	0.99	1.00	0.87	0.99	1.00	0.79

Notes: Spearman rank correlations between the baseline pillar and each variant, over the baseline's rankable cells (sovereign economies with at most half of the index weight imputed). "Pooled" is computed over all rankable cells of the eleven headline technologies; "Median" and "Minimum" are taken across technology–stage pairs of the correlation computed within each pair. For the Dirichlet draws the pooled entry is the median over 1,000 draws and the within-pair entries summarise, across pairs, each pair's median over the draws. The vintage rows compare the 2020 and 2025 builds of `scripts/40_build_index_vintages.R`, in which only the time-varying sources differ (4,139 ES and 4,301 EO rankable cells observed in both vintages), and the 2025 build with the headline index. Sample: 30 ES pairs (4,163 rankable cells) and 33 EO pairs (4,301 rankable cells). Entries are rounded to two decimals. Source: `scripts/paper/fig_robustness.R`; `paper/results/robustness.json`.

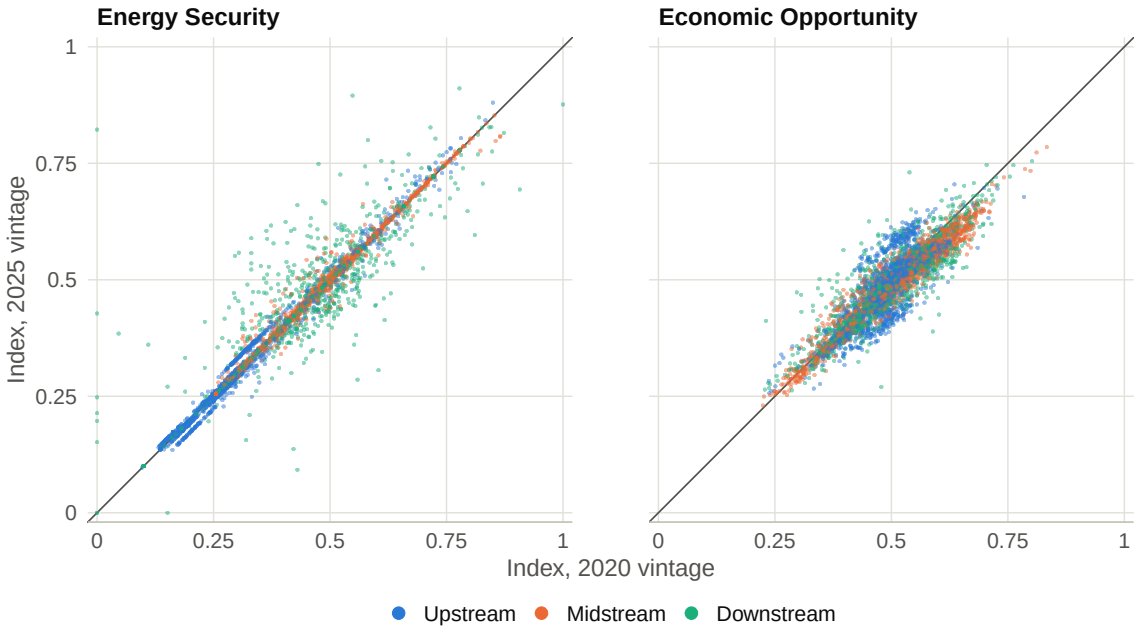

Figure OA.2: The 2020 and 2025 vintages of the pillars. Each point is a rankable country cell of the eleven headline technologies observed in both vintages (4,139 in ES, 4,301 in EO), coloured by stage; the line is the 45-degree line. Both vintages are built by `scripts/40_build_index_vintages.R` with the headline builders and configuration; only the time-varying sources are sliced to the vintage year, and Trade is measured on the Atlas basis. Source: `data/processed/vintages`; `scripts/paper/fig_robustness.R`.

categories, 34 per cent of the average ES cell's weight and 36 per cent of the average EO cell's re-derive. In ES (Figure OA.2) the mean absolute change is 0.015, 31 per cent of cells do not change, and the mean percentile shift is 3.8 points; 77 per cent of the squared Upstream changes is a common shift of whole pairs from the Energy Prices category, which is constant within a pair. In EO the mean absolute change is 0.030, no cell is unchanged and the mean percentile shift is 10.8 points, because Cost Competitiveness re-derives in every pair from annual earnings, lending-rate and producer-price series. Oil Downstream has the lowest correlation in both pillars (0.68 and 0.49). The largest single moves occur where a pair rests on one flow variable: in Electric Vehicles Downstream ES, built from annual GCIM flows alone, Viet Nam moves from 94th of 101 to 3rd. The 2025 vintage coincides with the headline except in Trade (median within-pair correlation 1.00 in both pillars; minima 0.87 in ES Nuclear Midstream and 0.79 in EO Nuclear Upstream, whose baskets the final revision changed). Because only about a third of the weight re-derives, the comparison likely understates instability over time; the vintage years are nominal for two sources (Atlas 2023 in the 2025 vintage, IMF producer prices 2021 in the 2020 vintage).

Category weights. The weight vectors are drawn as $w \sim \mathrm{Dir}(c\,\bar{w})$ around the configured shares $\bar{w}$, so that $E[w_k] = \bar{w}_k$ and the coefficient of variation of w_k is $\sqrt{(1-\bar{w}_k)/[\bar{w}_k(c+1)]}$; $c = 99$ for the ten categories of a pillar gives 0.3 for a category of average weight (Decancq and Lugo, 2013). In seven ES pairs and three EO pairs a single category varies, and there the ranking does not depend

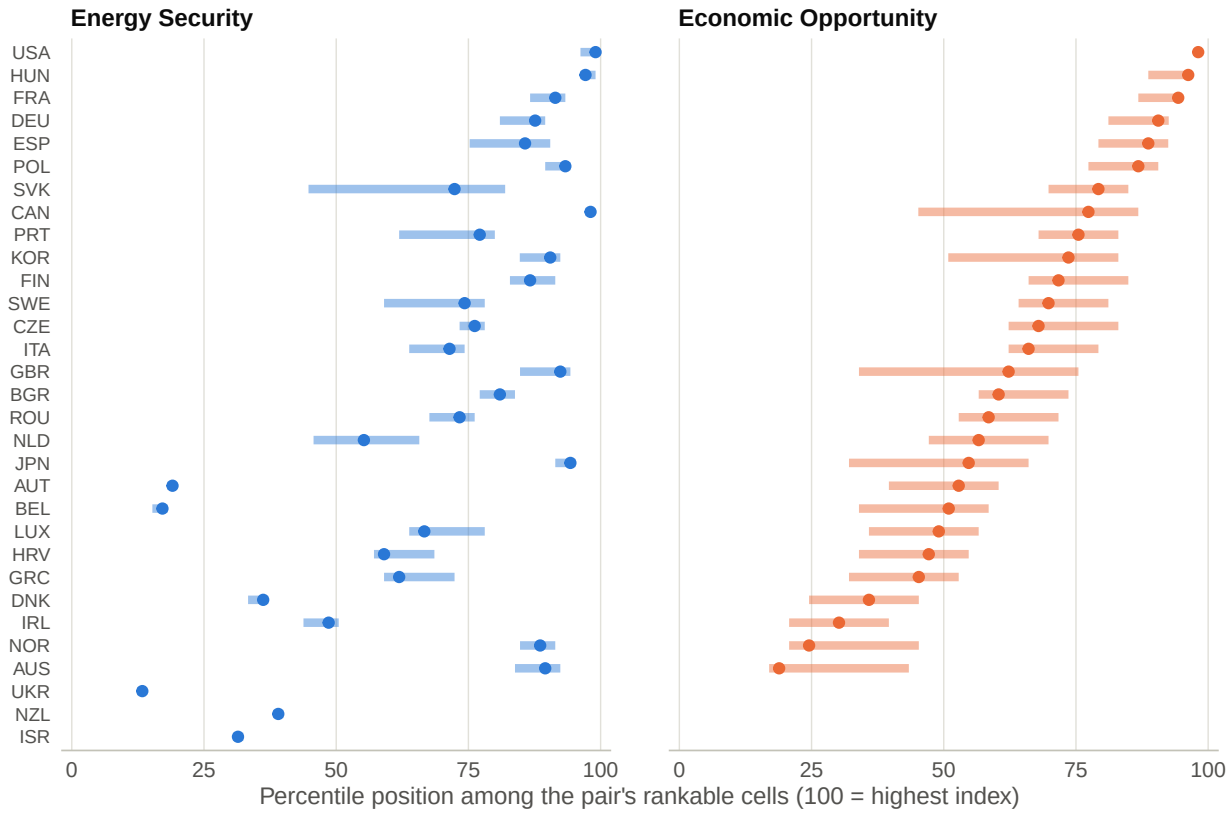

Figure OA.3: Rank uncertainty of the core members under perturbed category weights, Batteries Midstream. For each core member with a rankable cell (31 in ES, 28 in EO) the dot is its percentile position at the configured weights and the bar spans the 5th to 95th percentiles over 1,000 Dirichlet draws (coefficient of variation 0.3 for a category of average weight). Source: category scores in `index_outputs.rds`; `scripts/paper/fig_robustness.R`.

on the weights at all; on average 3 per cent of the observed weight of an ES pair and 25 per cent of an EO pair sits on categories constant within it. Restricted to pairs with two or more varying categories (23 in ES, 30 in EO), the median correlation over pair–draws is 0.996 and 0.987, but the minimum falls to 0.77 and 0.30. For each coalition member and pair, the 5th to 95th percentile band of its percentile position over the draws has a median width of 2.8 points in ES (1,606 member cells) and 9.6 in EO (1,718), with a 90th percentile of 18 and 31 points. Wide bands arise among large blocks of tied scores: in ES Batteries Downstream South Korea ranks 69th of 186 at the configured weights with a band from 15th to 186th; in EO the widest bands are Upstream, such as Brazil in Nuclear Upstream (163rd of 175, band 21st to 174th). Figure OA.3 shows one pair.

Curvature. Because $\operatorname{logit}\phi_\gamma(r) = \gamma \operatorname{logit} r$, a component at curvature γ' follows from the stored value as $\phi_{\gamma'}(r) = \operatorname{logistic}\left((\gamma'/0.5)\operatorname{logit}\phi_{0.5}(r)\right)$, which also maps anchored zeros to zero. The map is exact for a component that is a single S-curve of a rank; 46 of the 57 components that enter a scored category pass this test, carrying 84 per cent of the average ES cell's weight and 63 per cent of the EO cell's. For the others (the input- and levelised-cost terms, readiness, overcapacity,

Table OA.7: The rankability threshold: cells ranked, robustness of their rankings, and the Strategic Index

	ES			EO			Strategic Index			PSI
τ	Cells	ρ_{none}	ρ_{zero}	Cells	ρ_{none}	ρ_{zero}	Cells	Countries	Picks	Ranked
0.3	3,147	1.00	1.00	1,967	0.99	0.94	1,577	107	29/48	159/102
0.5*	4,163	1.00	0.98	4,301	0.97	0.77	3,154	174	57/57	192/188
0.7	5,350	0.99	0.98	5,974	0.86	0.68	5,156	194	42/57	194/194

Notes: A cell is rankable when the economy is sovereign and at most a share τ of its index weight rests on imputed components (* the headline, `config/rankability.yml`). Cells: rankable headline cells (of 6,232 scored ES and 7,131 scored EO cells). ρ_{none} and ρ_{zero}: median across technology–stage pairs of the within-pair Spearman correlation, over the cells rankable at τ, between the baseline pillar and the pillar rebuilt with every global-average rule removed (available case) or replaced by zero. Strategic Index: cells and countries in the sample when the pillars' rankable flags are taken at τ (the Policy index is unchanged), and the number of coalition members whose allied pick is the baseline one, over the members with a pick at τ. PSI: partners ranked in the core-coalition (headline) and world views. Within a technology–stage pair the order of two cells rankable under two thresholds is the same, because the rule filters cells and does not change values. Source: `scripts/paper/fig_robustness.R` (`rankability` in `paper/results/robustness.json`).

the production surplus of Energy Imports, the mineral-supply and production shares of Foreign Dependency, the minerals-trade terms and the geothermal and wind potential indices) it re-curves a mean and is an approximation. Levels move more than ranks: the mean absolute change of ES is 0.03, 0.04 and 0.08 at $\gamma' = 0.25$, 1 and 2.

Imputation. Nine ES themes and twelve EO themes fill uncovered countries with the observed mean of their component group (equation (14)). Such components carry on average 7 per cent of an ES cell's weight, mainly in Energy Access and Foreign Dependency, and 25 per cent of an EO cell's, two thirds of it in Technology Demand and most of the rest in Production and Cost Competitiveness. The lowest within-pair correlations are Nuclear Upstream (0.62) without imputation and Coal Downstream (0.58) with zeros in ES, and Coal Midstream (0.29) without imputation in EO. Zero-filling places every uncovered economy at or below every covered one on the component; removing the rule scores it on fewer measurements than its neighbours; the global average compresses the differences the component would make. None is neutral.

Rankability. Table OA.7 varies τ. Because the rule filters cells without changing values, it changes the sample, not the order of cells rankable under both thresholds. At $\tau = 0.3$ the rankable cells are 56 per cent of the sovereign scored cells in ES and 31 per cent in EO (74 and 67 per cent at the headline), at $\tau = 0.7$ 95 and 93 per cent. The median within-pair correlation of EO with its zero-filled variant is 0.94 at $\tau = 0.3$, 0.77 at the headline and 0.68 at $\tau = 0.7$. The top ten of 27 of the 30 ES pairs are identical at $\tau = 0.3$ but only 15 of the 33 EO top-ten lists. At $\tau = 0.3$, 48 of the 57 members keep a pick and 29 of them the baseline one; at $\tau = 0.7$, 42 of 57 keep the baseline pick. At $\tau = 0.3$ the world view of the PSI ranks 102 partners and the core view 159.

Leave one category out and effective importance. Figure OA.4 drops one category at a time. In ES the ranking depends most on Consumption (median within-pair correlation 0.74 over eight pairs) and Minerals Trade (0.79 over six); Trade has the widest range (minimum 0.40 in Electric Grid Midstream, whose basket the completed trade file filled) and is the only category of the four Midstream fossil and nuclear pairs. Production and Foreign Dependency, which share the largest nominal ES weight, change almost nothing (0.995 and 0.998). In EO, Foreign Dependency (0.75), Cost Competitiveness (0.76) and Trade (0.79) carry most of the ranking, while Technology Demand changes it little (0.99) and Technological Readiness and Energy Prices, constant within pairs, not at all. A complementary, exact measure is the share of a pillar's cross-country variance within a pair for which each category accounts. Because the pillar is the sum of its category contributions C_{kits} (equation (19)),

$$S_{kts} = \frac{\mathrm{Cov}_i(C_{kits},\, \mathrm{ES}_{its})}{\mathrm{Var}_i(\mathrm{ES}_{its})}, \qquad \sum_k S_{kts} = 1, \tag{OA.5}$$

and likewise for EO, a linear counterpart of the main effects of Paruolo et al. (2013). Table OA.8 compares nominal weights, mean effective weights and mean variance shares. The share of weight that would have to move for nominal and variance shares to coincide is 0.32 in ES and 0.37 in EO. In ES the gap is mainly coverage: Trade, observed in 18 of the 30 pairs, has 9.5 per cent of the nominal weight but 24.9 per cent of the effective weight and 21.5 per cent of the variance. In EO it arises within pairs: Technology Demand and Technological Readiness hold 21.8 and 14.6 per cent of the effective weight but 3.6 and 0.0 per cent of the variance, while Cost Competitiveness holds 21.9 and 32.8 per cent.

Strategic Index weights and policy variants. The Dirichlet draws of the five weights of equation (55) use concentration 43.4, giving coefficients of variation of 0.30 for the policy weight, 0.23 for the two pillar weights and 0.45 for the two priors. Indonesia keeps its pick in 15 per cent of the draws, its two leading sectors differing by 0.0007. Under security in place of need, 28 members pick Nuclear Midstream and 10 Gas Midstream; without the priors, ten picks move to Oil Midstream, the sector the technology prior penalises most; without the policy term, 20 members pick Nuclear Upstream instead of 8. Requiring both Policy components leaves 1,666 Strategic Index cells; dropping CAT for every country gives a median within-country Strategic Index correlation of 1.00 (interquartile range 0.91 to 1.00, minimum 0.30). The October 2026 NIPO component (GTA NIPO as of 5 October 2026, debiased strength; 1,070 rows), added with weights 4, 3 and 2 on NIPO, IEA PAMS and CAT and IEA PAMS still required, is observed in Upstream and Midstream cells only, in 841 Strategic Index cells (27 per cent); for its jurisdictions the within-country Spearman correlation between the policy ranks with and without it has a median of 0.88 (range 0.00 to 1.00), the pooled Strategic Index correlation is 0.97, and 27 of the 50 members with a NIPO score keep their pick.

Table OA.8: Nominal weight, effective weight and variance share of each category within technology–stage pairs

Category	Nominal share (%)	Effective weight (%)	Variance share (%)	Pairs	Leave-one-out ρ
*Panel A. Energy Security (*ES*), 30 pairs*					
Trade	9.5	24.9	21.5	18	0.93
Investment	7.1	11.3	18.1	12	0.92
Reserves	9.5	9.5	17.4	13	0.94
Consumption	11.9	15.8	13.2	9	0.74
Foreign Dependency	14.3	16.1	10.1	12	1.00
Production	14.3	5.8	10.0	7	0.99
Energy Access	9.5	7.2	5.0	6	0.89
Energy Imports	9.5	2.9	2.8	3	0.91
Minerals Trade	9.5	3.1	1.8	6	0.79
Energy Prices	4.8	3.4	0.0	10	1.00
*Panel B. Economic Opportunity (*EO*), 33 pairs*					
Cost Competitiveness	10.0	21.9	32.8	33	0.76
Trade	10.0	11.0	17.5	18	0.79
Investment	10.0	6.6	14.4	12	0.90
Production	10.0	8.1	12.5	16	0.95
Consumption	10.0	5.0	7.9	9	0.91
Foreign Dependency	10.0	2.9	7.4	5	0.75
Energy Access	10.0	2.8	3.8	6	0.91
Technology Demand	13.3	21.8	3.6	27	0.99
Energy Prices	10.0	5.3	0.0	10	1.00
Technological Readiness	6.7	14.6	0.0	33	1.00

Notes: Nominal share: $w_k / \sum_{k'} w_{k'}$ from `config/weights.yml`. Effective weight: mean over the rankable headline pairs of the weight $w_k / \sum_{l \text{ observed}} w_l$ a category receives after renormalisation over the observed categories; zero where the category is not observed. Variance share: mean over the same pairs of S_{kts} (equation (OA.5)), the covariance of the category's contribution with the pillar across the rankable cells of the pair divided by the pillar's variance; zero where the category is not observed. Each of the three columns sums to 100 within a panel up to rounding. Pairs: number of pairs in which the category is observed. Leave-one-out ρ: median, over the pairs in which the category is observed and the reduced pillar still ranks countries, of the within-pair Spearman correlation between the baseline pillar and the pillar without the category (Figure OA.4). Rows are ordered by the variance share. Sample: rankable cells of the eleven headline technologies. Source: category scores in `index_outputs.rds`; `scripts/paper/fig_robustness.R` (`weights.<pillar>.variance_importance` in `paper/results/robustness.json`).

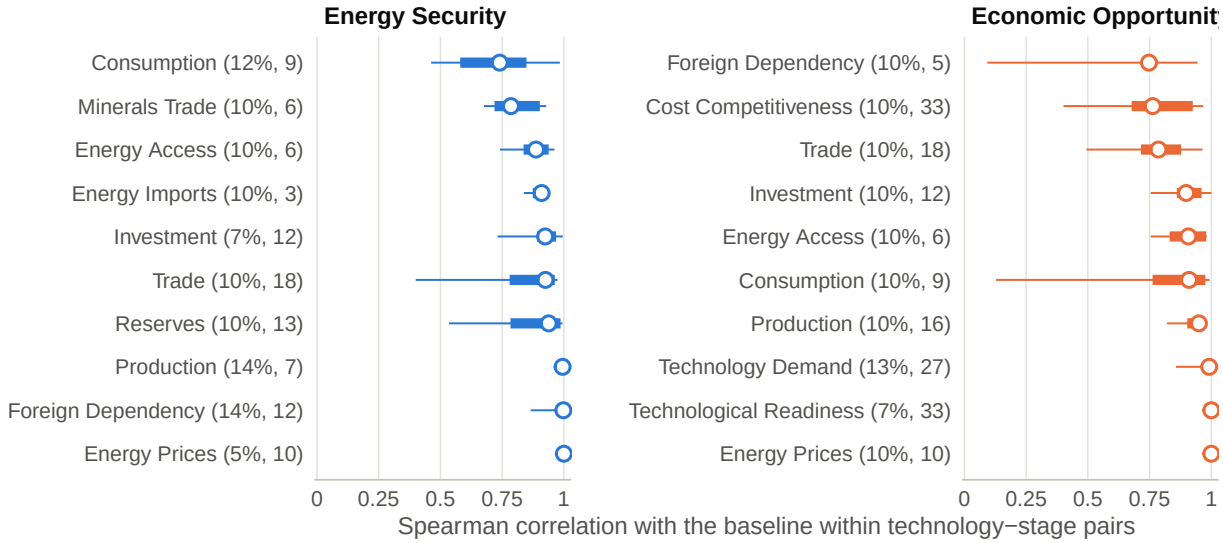

Figure OA.4: Leave-one-category-out sensitivity of within-pair rankings: Spearman correlation between the baseline and the pillar without the category (remaining categories renormalised), over the pairs in which the category is observed and the baseline's rankable cells; open circle, median; thick bar, interquartile range; thin line, range. Labels give the nominal weight share and the number of pairs observed. Pairs in which the dropped category is the only varying one are omitted. Source: `index_outputs.rds`; `scripts/paper/fig_robustness.R`.

Data choices of the final build. Table OA.9 and Figure OA.5 report the data choices of the last revision (11–12 October 2026). The headline carries 807 EIA-sourced rows in the import-dependence theme and 656 in the production theme; setting them to zero gives within-pair correlations of 0.97 to 0.98 in ES and 0.95 to 0.96 in EO in Oil, Gas and Coal Upstream. Removing Trade from the four Upstream cells with new baskets gives median within-pair correlations of 0.94 in ES and 0.73 in EO (minimum 0.58, Solar Upstream EO) and returns the Strategic Index to 192 countries, because the newly imputed Trade category had pushed small economies over the rankability threshold; three of the four changed picks move to Nuclear Upstream. The superseded energy-trade file is not kept, but interim builds record the picks: on 8 October, 45 of the 56 members then in the coalition had a pick, 17 Electric Grid Midstream and 11 Batteries Midstream; on 10 October, 4 and 26 of 57. Without Trade, Electric Grid Midstream picks rise to 10 and Batteries Midstream falls to 13; without Technological Readiness 32 of 57 picks survive (Electric Grid Midstream would take 27), without Technology Demand 41 and without Foreign Dependency 44. The CM-FDI comparison is not re-run on the final outputs, because the dyad tables exceed the memory budget of the replication; in the integration study, switching off the Chinese-parent component or the CM-FDI investment ties alone gives core-PSI correlations of 0.9999.

Vertical complementarities. The opportunity test regresses the five-year change in a stage's S-curved world market share, and entry into revealed comparative advantage, on the adjacent stage's market-share index, with country–year and technology–year fixed effects and standard errors

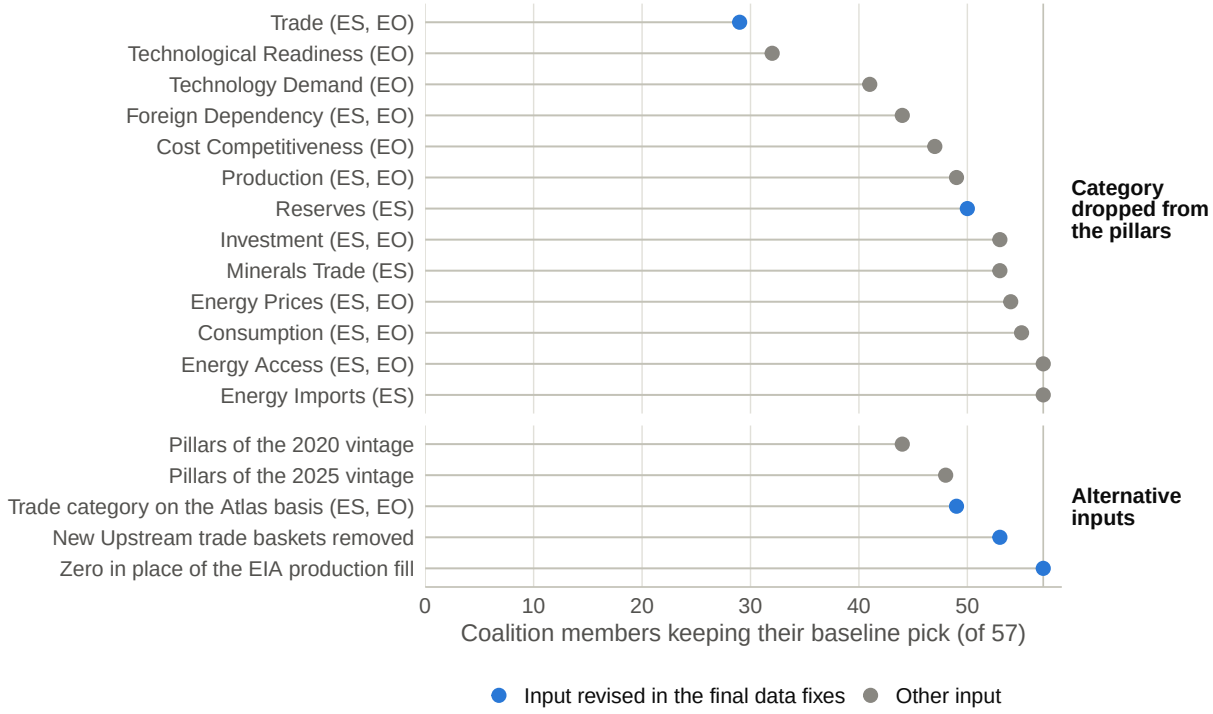

Figure OA.5: Stability of the allied picks under the data inputs: number of members, of 57, whose pick is the baseline one when the Strategic Index takes pillars rebuilt under a variant. Upper panel: one category dropped (without Trade three members have no eligible rankable sector, so 29 of the 54 with a pick keep it). Lower panel: pillars from the 2020 or 2025 vintage, Trade on the Atlas basis, Trade removed from the four Upstream cells whose baskets were added on 11 October 2026, and EIA-filled fossil production set to zero. Blue marks inputs revised in the final data fixes. The Policy index and the endowment screen are the headline ones. Source: `index_outputs.rds`, theme tables, vintages; `scripts/paper/fig_robustness.R`.

Table OA.9: Data and policy choices of the final build: rankable cells, rankings and allied picks

	Rankable cells		Median ρ, touched pairs		Strategic Index		
Variant	ES	EO	ES	EO	Cells	Countries	Same pick
Baseline	4,163	4,301	–	–	3,154	174	57/57
Data							
Zero in place of the EIA fill	4,164	4,301	0.98	0.96	3,155	174	57/57
New Upstream baskets removed	4,161	4,307	0.94	0.73	3,144	192	53/57
Policy index							
Both components required	=	=	–	–	1,666	65	46/46
IEA PAMS alone	=	=	–	–	3,154	174	45/57
October 2026 NIPO added back	=	=	–	–	3,154	174	34/57
Allied pick rule							
Endowment screen off	=	=	–	–	3,154	174	16/57

Notes: Rankable cells: headline cells of sovereign economies with at most half of the index weight imputed, after the variant (= unchanged). Median ρ: median across the touched technology–stage pairs (Oil, Gas and Coal Upstream for the EIA fill; Electric Vehicles, Wind, Nuclear and Solar Upstream for the baskets) of the within-pair Spearman correlation between the baseline and the variant over the baseline's rankable cells. Strategic Index: scored cells and countries, and the coalition members whose allied pick is the baseline one over the members with a pick. Zero in place of the EIA fill: the oil, gas and coal production that the Energy Institute does not report (807 EIA-sourced rows of the import-dependence theme and 656 of the production theme in the headline) set to zero, the rule until 11 October 2026, both themes rebuilt with the pipeline's builders. New Upstream baskets removed: the Trade category of the four Upstream cells whose trade baskets were added on 11 October 2026 dropped and both pillars rebuilt; the uranium codes moved out of Nuclear Midstream and the rare-earth codes moved out of EV and Wind Midstream are not restored. Policy rows as in Table 22. The partnership side is not rebuilt: in the CM-FDI integration study (inputs of 11 October 2026), switching off both CM-FDI parts of Friendshore gives a core-view PSI with a Spearman correlation of 0.9998 with the CM-FDI build over 192 ranked partners, a largest rank change of 5 places and 15 of the top 15 in common. Source: `scripts/paper/fig_robustness.R` (`data_choices` and `policy` in `paper/results/robustness.json`).

clustered by country. The cross-sectional association is positive and precisely estimated (0.046, standard error 0.007, for Midstream on Upstream; 0.102, standard error 0.015, for the reverse) but concentrated in fossil fuels and nuclear (0.062 and 0.151) and insignificant for the clean-technology chains (0.012 and 0.028); with country–technology fixed effects it is −0.001 (0.005) and 0.004 (0.015); lags of the stage's own capability absorb about a third of it; and it does not improve out-of-sample prediction (within-cell AUC for Midstream entry 0.800 without the term and 0.794 with it; 0.739 and 0.741 for Upstream). The 2023 co-location lift, the ratio of the joint to the independent probability of comparative advantage in both stages, is 4.4 for nuclear and 2.7 for coal but 0.97 for wind and below one for gas, electric vehicles and the grid. The security test builds the domestic share times the economy's own supply security plus the import-share-weighted security of its suppliers (half the supplier's ES in the input stage, half dyadic alignment). Its 2020 value does not predict import shortfalls in 2021–22 (0.10, standard error 0.31) or Midstream export growth after 2020 (0.02, standard error 0.19), whereas sourcing concentration does (negative, $p = 0.035$); the post-2022 shift of Upstream input trade towards aligned suppliers, 0.58 log points (0.11), falls to 0.07 (0.06) without Russia. Table OA.10 reports what the two terms would do at the evidence weights. The EO term, the adjacent stage's S-curved Atlas share minus the economy's mean of that measure over the nine basketed technologies, S-curved within the cell, enters with 0.07 weight points in Midstream and 0.23 in Upstream (0.6 and 1.5 per cent of a cell's mean observed weight): median within-pair correlation 0.999 (minimum 0.987), one pick changed (Luxembourg's, the smallest margin in the coalition), against 0 to 1 for a placebo with scores permuted within cells. The ES term at a 15 per cent share gives median correlations of 0.92 in Midstream and 0.91 in Downstream (minimum 0.56, Batteries Downstream) and changes 10 picks, against 11 (8 to 16) for the permuted placebo and 3 for a constant placebo that only rescales the other categories.

OA.11 Corrections to the shipped release: item detail

This appendix gives, for each item of Table 31, the defect, its symptom in the shipped release of September 2026, the correction and, where the audit measured it, the *pre-rerun effect*: the change the correction makes when applied alone to the theme tables and inputs saved with the shipped release. Pre-rerun effects isolate one correction on inputs that still embed the other defects; they are not results of the paper.

Aggregation (A1–A7). A1: an unobserved category kept its weight in the denominator and counted as zero, and a cell with no observed category scored zero; 1,809 of 2,773 headline ES Reserves rows were unobserved. The available-case rule alone changes 1,682 Upstream cells and raises mean Upstream ES by 0.139 (Oil), 0.112 (Gas) and 0.104 (Coal). Because the same commit gives Reserves a zero rule (the reserve tables list every material holder, so absence means none), the two changes offset on the shipped tables; the rule matters for categories without a missing-data rule and for the PSI (B4). A2: a zero or global-average rule filled groups in which no country was observed;

Table OA.10: Vertical complementarities: sensitivity of the pillars and the allied picks to an adjacent-stage term

Term	Weight	Median within-pair ρ	Minimum ρ	Picks changed
EO linkage, within-country deviation	Mid 0.07, Up 0.23	0.999	0.987	1
Placebo: scores permuted within cell	same	0.999 [0.999, 0.999]	–	0 [0, 1]
ES input security, sourcing-weighted	15% share	0.917	0.556	10
Placebo: constant 0.5	same	1.000	1.000	3
Placebo: scores permuted within cell	same	0.902 [0.891, 0.909]	–	11 [8, 16]

Notes: EO linkage: a category added to the Midstream and Upstream EO cells, the S-curved world market share of the adjacent stage (Atlas of Economic Complexity, HS92 baskets, 2023) minus the economy's mean of that measure over the 9 basketed headline technologies, S-curved within the cell (Midstream 1,890; Upstream 1,890 cells). Weights in EO weight points (the nominal category weights are 2 to 4): the evidence weights of the vertical-complementarity study, 0.6 times the ratio of the adjacent-stage to the feasibility coefficient in the five-year market-share regression, upper bounds because about a third of the coefficient is absorbed by lags of own capability. ES input security: the domestic supply share times the economy's own supply security plus the import-share-weighted security of its suppliers (half the supplier's ES in the input stage, half the dyadic alignment), 2024 sourcing, S-curved within the cell and given 15 per cent of the Midstream and Downstream cells' weight (Downstream 1,626; Midstream 1,893 cells). Median and minimum ρ: within-pair Spearman correlation with the baseline pillar over the baseline's rankable cells of the receiving stages; for the permutation placebo, the median and the 5th and 95th percentiles over 200 draws of the per-draw median. Picks changed: coalition members (of 57) whose allied pick differs from the baseline when the Strategic Index takes the modified pillar (for the placebo, median and 5th–95th percentiles over the draws). Neither term enters the headline indices. Source: `scripts/paper/fig_robustness.R` (`vertical` in `paper/results/robustness.json`), from the study's inputs.

it now fills only groups with an observed country and reports the rest. A3: `any(isTRUE(x))` is `FALSE` for vectors longer than one, so the diagnostics reported 11.9 and 29.5 percent of ES and EO category scores as imputed against 37.0 and 69.2 percent in fact; the final run has 38.4 and 45.0 percent. A4: Energy Prices was configured on a variable no theme produced and dropped from both pillars without warning, because the guard compared the join keys with themselves; it re-enters ten Upstream cells as a world price series that shifts cell levels and leaves within-cell order unchanged (Spearman 1.000 in every varying cell). A second guard now warns when a theme's own composite is scored in place of a configured overall. A5: an EO Reserves weight of 2 for a category EO does not have let resource-potential rows create 88 fully imputed EO cells (the Holy See, the Pitcairn Islands); EO falls from 6,923 to 6,835 headline cells. A6: the variable-contribution table divided by the number of components including missing ones; both decompositions now reconcile to the index (largest error 1.1×10^{-16}). A7: a development commit made `bind_rows()` read a named list of tables as one row; a rerun from that revision would have removed every overall-based category.

Country universe (C1–C3). C1: the standardiser attached ISO3 codes but did not rename rows, so the shipped ES, EO, Strategic and Policy tables carried 272 strings for 237 economies, with 30 codes under two or three spellings (Viet Nam and Vietnam, Korea and South Korea, the two Congos). Each spelling took its own rank in every S-curve with a partly observed, often imputed profile. Every variant now maps to the WDI name of its code (World Bank, 2026); territories with their own code stay separate. C2: the EI "USSR" series, a CIS aggregate, was coded RUS, "Northern Cyprus"

CYP, and a pseudo-country "Global" carried readiness values (128 rows); aggregates, residuals and historical entities are now dropped, not merged into successors. C3: the 2025 critical-minerals Comtrade pulls hold three reporters against about 130 in 2024; a vintage needs 50.

Energy Security themes (E1–E12). E1: graphite and rare earths fell out of every join because the IEA and EI name them differently; with harmonised names the rare earths carry about 79 percent of Wind's Mineral Supply weight. E2: the stage recode mapped refining to the Upstream under both branches; refining now scores the Midstream. E3: listed non-producers (Germany, Japan) tied at 0.441 just below the Congo at 0.473 in Batteries Upstream while unlisted economies scored zero; zero supply now maps to zero for every economy and suppliers rank above it. E4: the reserves roll-up averaged only over listed minerals, so Chile scored 1.000 on Wind Reserves on copper alone. E5: BNEF onshore and offshore wind were never recoded, so Wind had no Consumption category; growth was ranked across technologies; Viet Nam's rows fall from 160 to 63 once each country receives one regional value. E6: Minerals Trade kept only the market-share index; it is now the mean of a demand-weighted market share and a concentration index $\phi_\gamma(-\mathrm{HHI}_m)$. E7: critical-minerals investment was copied in full to Batteries and EV Upstream (79.8 each; now 9.2 and 70.6), and stage completion manufactured zero Investment cells in Nuclear Upstream and Midstream and Geothermal Upstream and Midstream, which made those cells constant across countries and gave Nuclear Upstream the maximum security need for every country. E8: electrolyser capacity was filed outside the headline technologies. E9: mineral Upstream production depth was an unweighted mean of different minerals' kilotonnes; it is now a demand-weighted share of world mined supply, with growth as an absolute change (EO moves by up to 0.067 in six cells, within-cell Spearman 0.955–0.992). E10: a placeholder region dropped the eight non-EU European EI economies from EV Midstream. E11: the EI "Import share" (a self-sufficiency ratio) and the EV "import_share" (a net-export ratio) are renamed for what they measure, and non-producers now tie exactly in Energy Imports. E12: an economy without its own EI production row (EI counts it in a regional residual) was read as producing nothing, so New Zealand counted as importing all its gas; production then comes from EIA International Energy Statistics (U.S. Energy Information Administration, 2026), flagged and counted as observed, paired with consumption of the same year (Estonia coal stays missing because EI counts oil shale). On the inputs of 10 October 2026 this moves 605 ES Upstream fossil cells and no allied pick.

Trade and Economic Opportunity (T1–T13). T1: the ES and EO trade themes were identical tables and the ES deficit term was never computed; ES Trade is now concentration, basket share and net basket imports over GDP, EO Trade share, RCA (Balassa, 1965), export size, feasibility and concentration (earlier–corrected Spearman 0.54–0.91 across cells). T2: export size and feasibility were ranked within reporter, so Moldova and Samoa ranked beside China in Solar Midstream. T3: market share was the export-weighted mean of product-level world shares; the Congo had 0.862 against a basket share of 0.0074 in Batteries Midstream. T4: ores, slag and scrap were filed under Batteries Midstream, untreated softwood logs under three grid and renewable baskets,

and 16 keys appeared twice. T5: 73 crosswalk codes had no HS92 counterpart, so the Atlas EV Midstream basket contained no cars; 19 predecessor codes bridge them. T6: the levelised cost entered Cost Competitiveness four times (0.78 of the category's weight where quoted). T7: readiness was written for a pseudo-country and reached real economies only by imputation. T8: Technology Demand listed composites beside their own sub-indices and ranked a zero addressable market as the smallest. T9: the export-concentration index was ranked across every basket, so unscored baskets (Semiconductors) moved scored cells; it is now ranked over the headline cells. T10: the Comtrade energy-trade file lacked 60 basket codes and 13 reporters, among them Qatar's LNG (USD 56.9bn in 2024); it is rebuilt from the World rows of the all-reporter dyad pull. T11–T13: duplicate WEO and BNEF demand keys, IEA 2035 manufacturing shares taken without the "Other" row (China's 2035 solar share 0.90 rather than 0.80), zero lending-rate stubs (New Zealand 0.0 percent, now 4.76) and mislabelled IMF price units (International Monetary Fund, 2026b); only the lending rates move an index value.

Policy and Strategic indices (P1–P9). P1: the NIPO module's jurisdiction weights overwrote the IEA module's, so international IEA policies were weighted 0.20 instead of 0.66. P2: Upstream stage tags matched substrings ("ore" in "more", "Korea", "Singapore"), tagging 36.9 percent of IEA policies Upstream; whole-word rules tag 12.5 percent. P3: name mismatches left South Korea, the United Arab Emirates (coded "UAE"), France, Italy and Denmark without a Policy index; EU members without a national CAT rating now take the EU's (Climate Action Tracker, 2026). P4: the policy block had stopped before writing its table since 6 February 2026, so the September Strategic Index combined September pillars with February policy components. P5: NIPO's default as-of date was the latest announcement or implementation date (1 October 2028 in every 2026 extract), counting scheduled measures as in force; it is now the extract's last announcement, capped at the release month and run date. NIPO is no longer in the composite; the robustness variant uses the October 2026 extract as of 5 October 2026. P6: the strategic table overwrote the security column with $1 - \text{ES}$; it now carries security and need under their own names (no value changes). P7: missing pillar or policy values were filled with country means (51 of 571 shipped cells); a cell now needs all three. P8: sectors with a constant pillar were not detected; Nuclear Upstream, constant at zero, was the top pick of 8 of 18 shipped allies. P9: the staged oil lifecycle emissions (720 g CO_2eq/kWh) appear in no IPCC table; the SRREN median of 840 (Moomaw et al., 2011) replaces it next to the AR5 values of the other technologies (Schlömer et al., 2014), so the oil weight falls from 0.12 to 0 and coal's rises from 0 to 0.02.

Bilateral indices (B1–B5). B1: grouped `transmute()` calls, name keys and a self-crossed backbone duplicated the Friendshore table (17.5 million rows for 1.44 million cells), so a dyad's best-five mean weighted its top cells 2, 2 and 1. B2: `mean(a:b)` returned `a`, so outward investment was the rank of the level only; 99 of 259 IMF counterpart names did not match, so China and the Netherlands scored zero from every reporter. B3: development potential, a partner-level construct, was stored per reporter with donor fan-out up to 38 rows, with 56 aggregates and mis-oriented WDI

series. B4: a high-income partner's undefined development score kept its weight, capping its PSI at 0.8 and placing the United States 185th of 218. B5: an opportunity column named for security held the partner's need, and the tables covered 18 to 20 pseudo-technologies rather than the eleven headline ones.

Network (N1–N7). These defects concerned the network design that the paper no longer uses; Appendix D records them, with the design itself, in one paragraph.
